

Solar Thermal Aquaculture System Controller Based on Artificial Neural Network

A. Doaa M. Atia, Faten H. Fahmy, Ninet M. Ahmed, and Hassen T. Dorrah

Abstract—Temperature is one of the most principle factors affects aquaculture system. It can cause stress and mortality or superior environment for growth and reproduction. This paper presents the control of pond water temperature using artificial intelligence technique. The water temperature is very important parameter for shrimp growth. The required temperature for optimal growth is 34°C, if temperature increase up to 38°C it cause death of the shrimp, so it is important to control water temperature. Solar thermal water heating system is designed to supply an aquaculture pond with the required hot water in Mersa Matruh in Egypt. Neural networks are massively parallel processors that have the ability to learn patterns through a training experience. Because of this feature, they are often well suited for modeling complex and non-linear processes such as those commonly found in the heating system. Artificial neural network is proposed to control water temperature due to Artificial intelligence (AI) techniques are becoming useful as alternate approaches to conventional techniques. They have been used to solve complicated practical problems. Moreover this paper introduces a complete mathematical modeling and MATLAB SIMULINK model for the aquaculture system. The simulation results indicate that, the control unit success in keeping water temperature constant at the desired temperature by controlling the hot water flow rate.

Keywords—artificial neural networks, aquaculture, forced circulation hot water system,

I. INTRODUCTION

THE shrimp farming is an important economical activity in many countries [1]. Intensive aquaculture is a modern cultivation way and it develops fast in many countries. Recently, People pay more and more attention on aquaculture for its advantages of high yield, no-time-limit, low-feed and high-utilization of water [2]. The purpose for applying process control technology to aquaculture in developed countries encompasses many socioeconomic factors, including variable climate. Anticipated benefits for aquaculture process control systems are to be increased process efficiency, reduced energy and water losses, reduced labor costs, reduced stress and disease, improved accounting, improved understanding of the process [3].

The study of artificial neural networks (ANN) is one of the two major branches of intelligence control, which is based on

the concept of artificial intelligence (AI). AI can be defined as computer emulation of the human thinking process. During the last ten years, there has been a substantial increase in the interest on artificial neural networks. During the last ten years, there has been a substantial increase in the interest on artificial neural networks. The ANNs are good for some tasks while lacking in some others. Specifically, they are good for tasks involving incomplete data sets, fuzzy or incomplete information and for highly complex and ill-defined problems, where humans usually decide on an intuitional basis [4-6]. In this paper the control of water temperature of aquaculture system is achieved. ANN control is chosen to this task due to high efficiency in control application.

II. MATHEMATICAL MODEL OF SOLAR THERMAL SYSTEM

Storage tank temperature is an important parameter which influences the system size and performance. Energy balance of a well mixed storage tank can be expressed as [5]

$$\rho V_s c_p \frac{dT_{st}}{dt} = q_c - q_l - q_{stl} \quad (1)$$

Where ρ water density (Kg/m³), V_s is storage tank volume (m³), T_{st} is storage tank temperature (°C), C_p is specific heat of water (4190 J/Kg °C), q_c is actual useful energy gain, q_l is load energy, and q_{stl} is storage tank losses.

A. Flat Plate Collector Modeling

Solar useful heat gain rate (q_c) from the collector array is calculated by

$$q_c = F_R A_c [\alpha\tau G - U_l (T_i - T_a)]^+ \quad (2)$$

Where q_c represents actual useful energy gain (W), F_R the collector heat removal factor, G intensity of solar radiation, in (W/m²), A_c collector surface area (m²), $(\alpha\tau)$ is the transmittance absorptance product, U_l is collector overall heat transfer coefficient (W/m²°C), T_a is the ambient temperature (°C), and T_i is the initial temperature. Where + sign indicates that only positive values of q_c is considered in the analysis. This implies that hot water from the collector enters the tank only when solar useful heat gain becomes positive [7].

B. Mathematical modeling of the aquaculture pond

All tables and figures you insert in your document are only to help you gauge the size of your paper, for the convenience of the referees, and to make it easy for you to distribute

preprints. A numerical model based on energy balance was developed to simulate the thermal behavior of the open-pond system. Assumed uniform temperature for the entire pond, and thus applied a well-mixed model [8].

1. Evaporation Losses

The evaporation heat loss is the largest loss component and is given

$$q_e = A_p P_a \left[35V + 43 (T_p - T_a)^{1/3} \right] (w_p - w_a) \quad (3)$$

Where q_e is the evaporation loss (W), V is the wind speed in (m/s) in the vicinity of the pond, P_a the ambient air pressure (101.3 k Pa). T_p is the pond temperature, T_a is the ambient temperature, w_p is the saturation humidity ratio at the pond temperature, w_a is the humidity ratio of the ambient air above the pond, A_p is the area of the pond [8, 9].

2. Convection Losses

Heat losses due to convection to the ambient air can be expressed as [6, 7]

$$q_c = w_e \times 0.0006 \frac{T_p - T_a}{w_p - w_a} \quad (4)$$

3. The Net Radiation Losses

Results from the surface of the pond to the sky which can be expressed as [8, 9]:

$$q_r = \epsilon \sigma A_p \left[(T_p + 273)^4 - T_s^4 \right] \quad (5)$$

Where q_r is the radiation loss, ϵ is the emissivity of the surface, σ is the Stefan-Boltzmann constant, T_s is the sky temperature in degrees Kelvin, T_p is the pond temperature.

4. Solar Radiation Heat Gain

Heat gain due to the absorption of solar radiation by the pond is given by [8, 9]

$$q_s = \alpha A_p G \quad (6)$$

Where α is pond absorptance (0.9).

C. The Control Thermostatic Valve Modeling

The required characteristic of this valve must be linear, such that controlling the valve input signal, will directly control the mass flow rate of water. Therefore, the transfer function of the used valve will be considered to be a first order one, as

$$G_v(s) = \frac{1}{s + 1} \quad (7)$$

D. Required Pond Design

The pond is selected to be a rectangular shape as shown in Fig 1. The parameters of the pond are indicated in table 1.

TABLE I THE POND DIMENSION

Length (m)	L	20
Width (m)	W	8
Depth (m)	d	1.22
Volume (m ³)	V	168
Area (m ²)	A	64

Fig. 1 pond design (a) Pond dimension (b) Pond cross section detail.

III. NEURAL NETWORK DESCRIPTION

In recent years, neural solutions have been suggested for many industrial systems using either feed-forward or recurrent neural networks. The ANN is usually made up of activation function neurons and training algorithm is normally used to train the network either online or off-line. Some applications use neurons with a radial base activation function. The ANN may play different roles: plant identification, non-linear controller, and fault signaling. Typical neural networks used for identification purposes are multilayer feed-forward structures containing neurons with activation function. There are two configurations for plant identification: the forward configuration and the inverse configuration [10-12]. A neural network consists of a number of processing elements "neurons" each of which have many inputs but only one output. In a typical network there are three layers of neurons, which are input layer receives input from the outside world, hidden layer which receive inputs from the input layer neurons and the output layer which receives inputs from the hidden layers and passes its output to the outside world and in some cases back to the preceding layers. In a feed forward neural network, the value of each node in a particular hidden layer is the result of a non linear transfer function a whose argument is the weighted sum over all the nodes in the previous layer plus a constant term b which is referred to as the bias as presents in Eq. 8

$$x_i = \sum_j y_j W_{ij} + b \quad (8)$$

The j subscript refers to a summation of all nodes in the previous layer of nodes and the i subscript refers to the node position in the present layer. In order to solve for the weight and bias values of Eq.8 for all nodes, one requires a set of input patterns, representative of the system behavior. A variety of training algorithms are available but in general, to train a network, one begins with a set of training data consisting of the input vector, and corresponding target vector. The internal weights are adjusted until the sum of differences between the neural network outputs and the corresponding target is minimized to a pre-determined level for all the training data. A sigmoidal function is usually used for the transfer function as it enables a finite number of nodes in a single hidden layer to uniformly approximate any continuous function

$$y_j = \frac{1}{1 + e^{-x_j}} \quad (9)$$

A. The Error Back-Propagation Algorithm

The most popular supervised training algorithm is the one named 'error back-propagation', or simply 'back-propagation'. It involves training a FFANN structure made up of activation function neurons. The back-propagation algorithm is a gradient method aiming to minimize the total operation error of the neural network. The process is intended to minimize the Error between the network output and the output actual output for the same input. The total error is a function defined by

$$RMS = \frac{1}{2} \sum_j |t_j - o_j|^2 \quad (10)$$

Where t is target value, and o is output value [10-14].

B. Neural network advantages

- ANNs are able to learn the key information patterns within a multi dimensional information domain.
- The inherently noisy data do not seem to cause a problem, since they are neglected. ANN models represent a new method in system prediction.
- ANNs operate like a black box model and do not require detailed information about the system.
- Instead, they learn the relationship between the input parameters and the controlled and uncontrolled variables by studying previously recorded data, similar to the way a non linear regression might perform.
- ANNs has the ability to handle large and complex systems with many interrelated parameters.
- Artificial neural networks differ from traditional simulation approaches in that they are trained to learn

solutions rather than being programmed to model a specific problem in the normal way.

- They are used to address problems that are intractable or cumbersome to solve with traditional methods.

IV. PROPOSED CONTROL SYSTEM

The neural network is utilized to provide the system with the required control. Thermostatic valve is used to adjust the hot water mass flow rate through the system to control the pond temperature at 34 °C. The proposed control system consists of the ANN controller which is used to control water temperature. The control signal is used to control the operation of thermostatic valve to control the hot water flow rate added to the pond as depicted in Fig.2.

Fig. 2 Block diagram of pond temperature control using NN control.

V. ANN CONTROL

Fig. 3 Neural network controller architecture.

The proposed NN control after many trials, shown in Fig.3, eventually employed three layers which are the input layer, hidden layer, and output layer. The input layer consists of three neurones which are the air temperature, pond temperature and error, hidden layer consists of seven neurones, and output layer of one neurones as shown in Fig. 3. The activation function used in this work is "logsig" for hidden layer, and "purelin" for output layer. The NN is trained using a back propagation with Levenberg-Marquardt algorithm. The Back propagation is a form of supervised learning for multi-layer nets. Error data at the output layer is back propagated to earlier ones, allowing incoming weights to

these layers to be updated. It is most often used as training algorithm in current neural network applications. Figure 4 presents the mean square error between the network output and the target. The network response analysis is depicted in Fig. 5 As shown in the figure the regression "R" equal one which mean the output track the target in a correct way.

Fig. 4 Mean square error.

Fig. 5 Regression between the network output and target.

VI. SYSTEM SIMULATION

The simulation model of the proposed thermal system is depicted in Fig. 8. The system consists of solar thermal subsystem to feed the system with the required hot water during the day, biogas subsystem is the auxiliary heater, pond subsystem, and finally the control subsystem. MATLAB SIMULINK of NNC is depicted in Fig. 7. Fig. 8 indicates the weight block diagram of layer1.

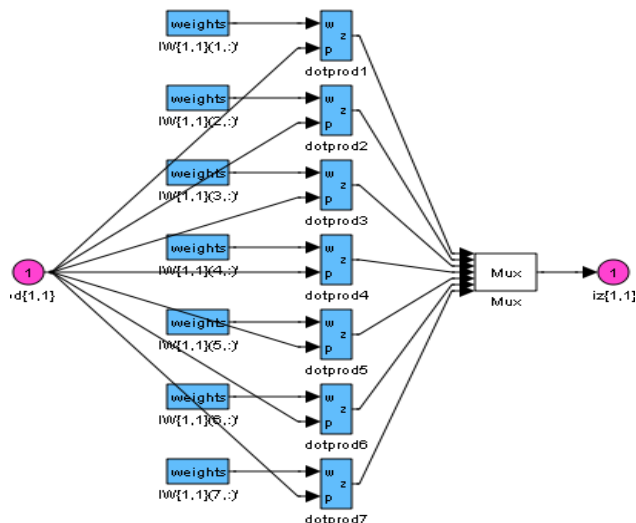

Fig. 8. Block diagram of layer 1 weights

VII. RESULTS AND DISCUSSION

The results of the MATLAB software indicate the high capability of the proposed technique in controlling the water temperature in the aquaculture pond, even in case of changing atmospheric conditions. The system has two input parameters they are air temperature, and solar irradiance. Figure 9 and Fig. 10 represent solar irradiance in Mersa Matruh the site of consideration in summer and winter respectively. Figure 11 and Fig. 12 show the air temperature in summer and winter.

Figure 13 and Fig. 14 indicate the pond temperature in summer and winter respectively. It is shown that the NN control has adjust the water temperature at 34oC without any variation during the day. Any variation in water temperature will harm the shrimp life, so the NN control has successes in this process. Figure 15 and Fig. 16 show the hot water flow rate variation over the day in summer and winter respectively. It is clear that as air temperature increase the pond temperature increase, so the value of mass flow rate decreases. During the night hours the mass flow rate has high value rather than that the day hours. The mass flow rate in winter is higher than in summer because of low air temperature in winter than in summer. The simulation results show the high efficiency of the proposed control system in control pond water temperature.

VIII. CONCLUSION

The most important parameters to be monitored and controlled in an aquaculture system are related to water quality, since they directly affect animal health. Neural networks offer one such method with their ability to map complex nonlinear functions. Neural networks are massively parallel processors that have the ability to learn patterns through a training experience. Because of this feature, they are often well suited for modeling complex and non-linear processes such as those commonly found in the heating system. This paper introduces the NN technique to control the water temperature of aquaculture pond. The air temperature, pond temperature, and error are used as inputs to NN control. Offline training applied with the BP has been used. The simulation results show that the feasibility of NN control in keeping water temperature constant at the desired degree (34°C) by adjust the mass flow rate of hot water to the pond.
