

TABLE I
 CLASSIFICATION OF URDU LETTERS BASED ON THEIR SHAPES IN CURSIVE FORM

Members	Classes	Members	Classes	Members	Classes
م	م	ص ض	ص	ا آ	ا
و	و	ظ ط	ظ	ب پ ت ٹ	ب
ہ	ہ	ع غ	ع	ج چ ح خ	ج
ھ	ھ	ف ق	ف	د ڈ ذ	د
ی	ی	ک گ	ک	ر ژ ز	ر
ے	ے	ل	ل	س ش	س
ق	ق	ف	ف	ن	ن

Urdu can be written with different styles. Nastalique, Naskh, Kofi, sals, devani and Raka are the different styles of writing Urdu [6]. Today most commonly used script are Nastalique and Naskh. The figure below tells how these different styles look like.

نستعلیق	وَسَخَّرَ الشَّمْسَ وَالْقَمَرَ
نسخ	وَسَخَّرَ الشَّمْسَ وَالْقَمَرَ
کوفی	وَسَخَّرَ الشَّمْسَ وَالْقَمَرَ
ثلث	وَسَخَّرَ الشَّمْسَ وَالْقَمَرَ
دیوانی	وَسَخَّرَ الشَّمْسَ وَالْقَمَرَ
رقاع	وَسَخَّرَ الشَّمْسَ وَالْقَمَرَ

Fig. 4 Different writing styles for Arabic script. Figure taken from [6].

A. Nastalique Script

Nastalique is a combination of two different fonts, Naskh and Taleeq. It was initially created by Mir Ali Tabrezi. The calligrapher tends to increase the beauty of the script and making it a complex script. It is highly cursive and context sensitive in nature.

Some of the characteristics are as follows:

1. It is written diagonally from top right to bottom left. That means all the ligatures are tilted at a certain angle towards the right side as shown below. Due to this diagonal nature the nastalique consumes less horizontal space as compared to Naskh [2].

Fig. 5 Nastalique style (top) takes less horizontal space than Naskh style (bottom) for the same text [1]

2. The joins are formed by cusp-like shapes, which are concave upwards and have their initial end higher than the final end [2].

Fig. 6 Cusp like joint are marked with red

3. Overlapping problem is present in characters and ligatures [2]. For example kaf of the word “kisam” is overlapping “meem” of tamam.

Fig. 7 Overlap between the ligatures

4. Context Sensitive nature of nastalique compels the letters to adapt different shapes [6].

Following figures are taken from [2]

<table border="1"> <tr><td>ح</td><td>ح</td><td>ح</td><td>ح</td><td>ح</td></tr> <tr><td>ح</td><td>ح</td><td>ح</td><td>ح</td><td>ح</td></tr> <tr><td>ح</td><td>ح</td><td>ح</td><td>ح</td><td>ح</td></tr> <tr><td>ح</td><td>ح</td><td>ح</td><td>ح</td><td>ح</td></tr> </table> <p>Initial Shapes of Hay</p>	ح	ح	ح	ح	ح	ح	ح	ح	ح	ح	ح	ح	ح	ح	ح	ح	ح	ح	ح	ح	<table border="1"> <tr><td>ح</td><td>ح</td><td>ح</td><td>ح</td><td>ح</td></tr> <tr><td>ح</td><td>ح</td><td>ح</td><td>ح</td><td>ح</td></tr> <tr><td>ح</td><td>ح</td><td>ح</td><td>ح</td><td>ح</td></tr> <tr><td>ح</td><td>ح</td><td>ح</td><td>ح</td><td>ح</td></tr> </table> <p>Medial Shapes of Hay</p>	ح	ح	ح	ح	ح	ح	ح	ح	ح	ح	ح	ح	ح	ح	ح	ح	ح	ح	ح	ح

III. METHODOLOGY

Mostly the work that is available today is on Arabic OCR. Little effort has been made on Urdu OCR and especially on Nastalique Urdu OCR [17, 18, 19, 20, 21, and 22]. The cursive and context sensitive nature of the script complicates the situation even further.

For recognizing cursive script, there are two main approaches to deal with connected characters in a word.

1. Segmentation based Approach
2. Segmentation free Approach

Due to highly cursive nature the segmentation of Urdu script is not a trivial task. So we will discuss segmentation free approach in which the ligature as a whole is used instead of segmenting it into smaller units. Different pattern matching techniques are used to classify the pattern. Most commonly used method in this approach is to extract features from the image and feed them to some recognizer for identification purpose. Three types of features are normally extracted which are transformational [7, 8], statistical [9, 10, 15] and structural [13].

In our research, we extracted global transformational features from a non segmented ligature and then fed them to Hidden Markov Model (HMM) recognizer. HMM has an ability to perform recognition with great ease and efficiency. Language-independent training and recognition methodology was a major reason of using HMM in developing recognition technology [11]. Hidden Markov model Tool Kit (HTK) [12] is used to implement HMM.

The Process of HMM recognition is divided into two tasks.

1. Training
2. Recognition

A. Training

Before starting the recognition process, the system is properly trained on each unique HMM (training data) [16]. Each connected body is considered as a separate HMM. Connected body may be a diacritic or a main body. A separate recognizer for diacritics and main bodies are built. Diacritic Recognizer is trained on one dot, two dots, three dots, Shad, Mad, Secondary Stroke of hey, Secondary Stroke of gaf, Khari Zabar, Do Zabar, Hamza and small toey. Main Body Recognizer is trained on 1500 high frequency ligatures which vary from one character ligature to seven characters ligature. In order to cater all sorts of noise and variations in the image we need to collect at least 30 samples of each HMM model.

The figure below gives the overall flow of the process.

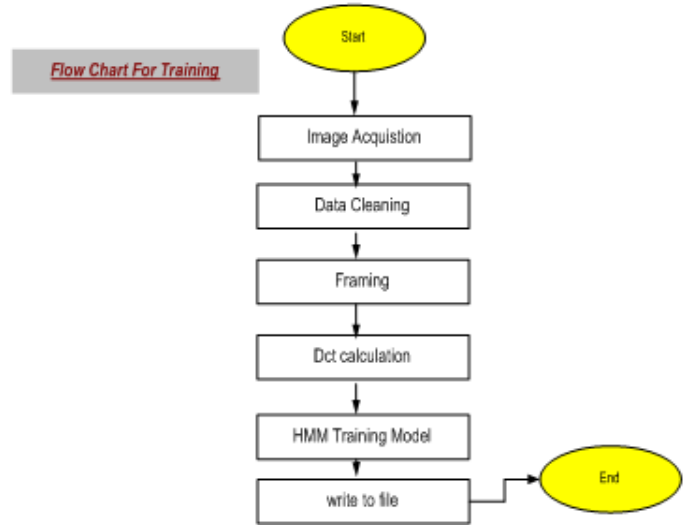

Fig. 9 Flow Chart of Training

TABLE II
 HMM MODELS FOR MAIN BODY RECOGNIZER

h022	h0366	h0429
h0528	h0626	h013
h061	h0620	h0616

For main body Recognizer not only the HMM models are trained but a lexicon is also maintained at the time of training which tells about all the character classes within each model. Entry for each HMM model is incorporated in the lexicon. The following table gives some of the entries of lexicon to identify the character classes with in the ligature.

TABLE III

SOME OF THE ENTRIES OF LEXICON TO IDENTIFY THE CHARACTERS CLASSES WITHIN THE LIGATURE

Main Body	HMM Model	Rule
	h061	(ٲ) class+ (ٲ) class+(ٲ) class+(ٲ) class + (ٲ) class+(ٲ) class
	h022	(ٲ) class + (ٲ) class
	h0366	(ٲ) class+ (ٲ) class + (ٲ) class
	h0616	(ٲ) class+ (ٲ) class+(ٲ) class+(ٲ) class + (ٲ) class + (ٲ) class

B. Recognition

Once all the models are properly trained, the system is ready for recognition. The overall flow of recognition process is given in the figure below. After separating and re-associating the diacritics and main body, each connected body is further divided into small chunks/windows called frames. The discrete cosine Transform (DCT) is calculated for each frame and then fed to HMM recognizer. The information regarding the location of the diacritic is also stored which will be in the recognition phase.

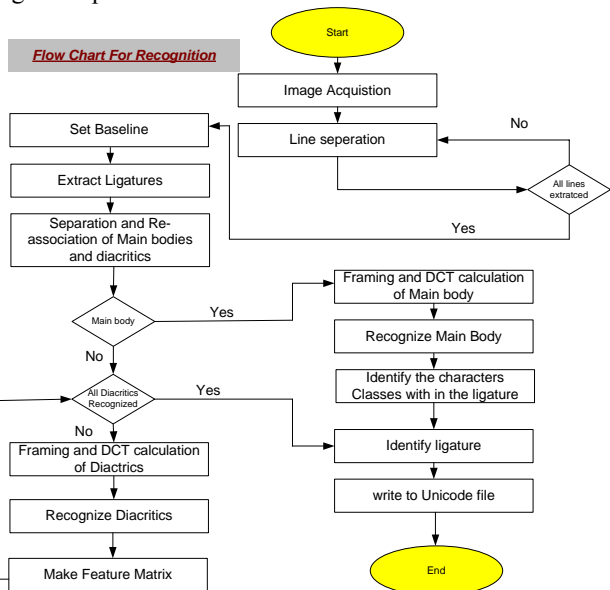

Fig. 10 Flow Chart for Recognition

Diacritics are divided into vertical windows of size 9x25 whereas main body is divided into vertical windows of size 8x90. 1 bits are padded to complete the window. The direction of frame traversal is from right to left as shown below. Let's take an example of the Urdu letter "ب" and see how framing is done for its diacritic and main body.

Fig. 11 Framing in main body and diacritic.

C. Feature Matrix

Once the diacritics are recognized, feature vector is prepared according to the information of diacritics. If no diacritic is present then the vector is '0'. If the diacritics are present then after recognizing them we make the vector as shown below.

We used the following codes for making feature matrix:

TABLE IV
CODES FOR MAKING FEATURE MATRIX

Main Body	Rule
1 dot above	01
2 dots above	02
3 dots above	03
1 dot below	04
2 dots below	05
3 dots below	06
Shad	07
Mad	08
Secondary Stroke of Hey	09
Secondary Stroke of Gaaf	10
Khari zabar	11
Do zabar	12
Hamza	13
Small toey	14
1 dot in the middle	16
2 dots in the middle	17
3 dots above in the middle	18
3 dots below in the middle	19
Hay in the middle	20
Hamza in middle	21
Small Toay in the middle	22

For example the feature matrix for the ligature “غتبٹ” is give as below-

Feature Matrix:

14	16	02	01
----	----	----	----

D. Recognizing the ligature

After recognizing the main body, the already developed lexicon is used to identify the classes of the characters with in the ligature. Once the classes are identified, next step is to exact characters within the ligature. For this purpose rule based recognizer is used. Feature matrix along with the identified classes is fed to rule based recognizer which then correctly recognizes the ligature. Some of the rules are listed below.

TABLE V
 RULES FOR LIGATURE CREATION

Sr.	Identified classes	Feature Matrix	Rule
1	(ل) class + (ب) class	01	نا
2	(ل) class + (ب) class	06	با
3	(ل) class+ (ب) class+(ب) class	04 05 14 01	بیٹھنے
4	(ل) class+ (ب) class+(ب) class+(ب) class	04 05 14 02	بیٹھنے

As the characters are identified, their respective Unicode is also written in the file which gives us the required ligature.

Let's take an example of the following ligature and see how it is recognized.

Fig. 12 Ligature to be recognized

First of all diacritics and main bodies will be separated and location of both the diacritics is store. The first single dot is marked as middle and two dots as above. Then main body and all the diacritics are sent to their respective recognizer.

Main body	Diacritics	
	 (1)	 (2)
h061	h01	h02

Fig. 13 Diacritics Separated from Main body

Main body recognizer will give us h061 as the identified model; similarly output of diacritic recognizer will be h01 and h02. These HMM numbers tell us the type of the pattern recognized. h01 and h02 tell that diacritic (1) is one dot and diacritic (2) is two dots respectively. Model h061of main body tells that it is six characters word with the following classes.

(ل) class+ (ب) class+(ب) class+(ج) class +(م) class+ (س) class

Next step is to prepare a feature vector. It has one dot in the middle and two dots above so the feature vector will look like the following.

Feature Matrix:

16	02
----	----

(ل) class+ (ب) class+(ب) class+(ج) class+(م) class+ (س) class +	16	02	غتبٹ
---	----	----	------

Then the Unicode for all these characters are written in the text file such that a ligature is formed.

IV. RESULT

A total of 1282 unique ligatures are extracted from the 5000 high frequency words in a corpus-based dictionary [14]. It is also confirmed that all Urdu letters are used in these ligatures in a variety of contexts. For analysis purpose three or more samples of each ligature are taken to form the text. These pages are printed in Noori Nastalique font at font size 36. The pages are then scanned at dpi 150 and then separated back into ligatures. A total of 3655 ligatures are tested and 3375 ligatures are accurately identified, giving an accuracy of 92%.

V. DISCUSSION

Testing and further analysis shows the following reasons for the errors.

Sometimes the shapes of different ligatures are so similar that they give approximately same state transition probabilities. So when these inputs are given to HMM for recognition same

state sequence of HMM is obtained. Erroneous output is thus obtained due to the slight similarity in shape. The shape of the ligatures “تسبر” and “تسبر” are similar to each other when written in Noori Nastaleeq font. Sometimes the OCR is not able to recognize ligatures like these correctly because of the similarity in shape. Another such problem can be seen in “گم” and “گن”. Both these ligatures are more similar than different. Sometimes they are recognized correctly and sometimes they are not. This problem can be removed by making the sliding window over-lapping. By using overlapping windows finer details of ligature shape can be also be covered.

Sometimes due to noise or poor scanning the actual shape of the diacritic is distorted. In this case, the diacritic is not recognized correctly and as a result incorrect feature vector is made. Thus the ligature is not recognized. During scanning the diacritic “” is distorted. Total number of windows and DCT values differ to great extent. This results in erroneous recognition of diacritic. Increasing the number of samples, while training, can improve the accuracy.

For recognizing a ligature we first identify its shape and then recognize it by seeing the class of feature vector which it belongs to. Sometimes it so happens that 2 different ligatures have exactly the same feature vector though position and location of dots are different. In this case the result is erroneous due to the same feature vector. In Ligatures “ذع” and “دع” the shape of main body is same and the feature vector of both the ligatures is “01”. Due to the same feature vector and main body, these ligatures can't be trained and recognized at the same time. Another such problem can be seen in the ligatures “رضخ” and “رضح”. These ligatures too have same shape of main body and the feature vector in both these ligatures is “02”. Only one of them can be recognized at a time.

VI. CONCLUSION

The Nastalique script is complex due to its context sensitive and cursive nature. The absence of baseline and complex mark placement rules makes the situation even more worst. So the extraction of Nastalique text from the image is not a trivial task. The algorithm has been developed which successfully extracts the texts with an accuracy of 92%.
