Application of $H_2$-based Sliding Mode Control for an Active Magnetic Bearing System

Abdul Rashid Husain, Mohamad Noh Ahmad, and Abdul Halim Mohd. Yatim

Abstract—In this paper, application of Sliding Mode Control (SMC) technique for an Active Magnetic Bearing (AMB) system with varying rotor speed is considered. The gyroscopic effect and mass imbalance inherited in the system is proportional to rotor speed in which this nonlinearity effect causes high system instability as the rotor speed increases. Transformation of the AMB dynamic model into regular system shows that these gyroscopic effect and imbalance lie in the mismatched part of the system. A $H_2$-based sliding surface is designed which bound the mismatched parts. The solution of the surface parameter is obtained using Linear Matrix Inequality (LMI). The performance of the controller applied to the AMB model is demonstrated through simulation works under various system conditions.

Keywords—Active Magnetic Bearing (AMB), Sliding Mode Control (SMC), Linear Matrix Inequality (LMI), mismatched uncertainty and imbalance.

I. INTRODUCTION

SLIDING Mode Control (SMC) has received great attention in recent years because of its robustness against uncertainties present in system [1], [2], [3] and [4]. SMC is a nonlinear control technique that is applicable to a wide range of dynamic system including the linear, nonlinear, multi-input/multi-output, discrete-time and large scale systems. There are many approaches have been reported and considered in the design process of the sliding-mode control law, such that the system is robust or even insensitive to parametric uncertainties and disturbance. In the practical application of SMC, the controller has also been successfully adapted in many forms and applied in numerous real-world applications such as robot manipulator [5], active suspension system [6], magnetic suspension system and magnetic bearings [7][8].

AMB system however is an advance mechatronic system in which it open loop unstable and inherent high nonlinearity effect. Thus the system requires feedback gain such that the closed-loop system is stable and able to meet required system performance. Although the system is complex in term of its structural and control design, the advantages it offers outweigh the design complexity. Thus stabilization of the system to meet various application needs has offered great challenges to control research group.

The main objective of this work is the application of the SMC technique to the AMB system. The design of SMC controller involves two crucial steps which are commonly referred to as the reaching phase and the sliding phase [1][2]. In this paper, the latter one which is the design of the sliding surface using $H_2$ guaranteed cost surface based on work in [9] is of more emphasis. The work in [9] is the extension of the surface design reported in [4] and elaborated extensively in [2]. In [10], the application of the $H_2$ designed surface based on [4] with a new SMC controller into AMB system is explored in which the result shows that the present of mismatched system uncertainties and disturbance may cause degradation of system performance. Thus, based on the surface design outlined in [9] and control law in [2], the performance of the AMB system with the present of the mismatched system uncertainty and disturbance is investigated through simulation work. The design steps as well as the necessary theoretical background are outlined in which based on the final result, it is shown that the proposed method gives an improved system performance.

The outline of this paper is as follows: In Section II, the model of the AMB system based on [8] is illustrated. Section III covers the detail design of sliding surface wherein the optimal parameter is obtained by solving an LMI optimization problem. Then, in Section IV, the performances on the AMB system under the designed controller are illustrated through simulation works under various system conditions. Finally, the conclusion in Section V summarizes the contribution of the work.

II. MODELING OF AN ACTIVE MAGNETIC BEARING SYSTEM

In order to synthesize the proposed sliding surface with the controller, a vertical shaft AMB system model for the application of turbo molecular pump system is re-derived based on the work done in [8].

A. Mathematical Model

The gyroscopic effect that causes the coupling between two axes of motions (pitch and yaw). Fig. 1 illustrates the five DOF vertical magnetic bearing in which the vertical axis ($z$-axis) is assumed to be decoupled from the system and hence
Fig. 1 Vertical Active Magnetic Bearing System

controlled separately. The top part of the rotor of the system in Fig. 1 is controlled actively by the magnetic bearing, labeled as AMB, in which the coil currents are the inputs. The bottom part of the rotor however is levitated to the center of the system by using two sets of permanent magnets labeled as PMB. The rotation of rotor around the z-axis is supplied by external driving mechanism and considered as a time-varying parameter.

Fig. 2 illustrates the free-body diagram of the rotor which shows the total forces produced by the AMB and PMB of the system. Based on the principle of flight dynamics [11], the equations of motion of the rotor-magnetic bearing system is as follows:

\[ \begin{align*}
    m_i \ddot{X}_i & = f_{xi} + f_{ui} + m_i \omega^2 \cos(\omega t) \\
    J_i \dot{\beta} & = -J_i \omega \dot{\alpha} + L_i f_{xi} - L_x f_{ui} \\
    m_i \ddot{Y}_i & = f_{yi} + f_{ui} + m_i \omega^2 \sin(\omega t) \\
    J_i \dot{\alpha} & = J_i \omega \dot{\beta} - L_x f_{xi} + L_y f_{ui}
\end{align*} \] (1)

The terms \( m_i \omega^2 \cos(\omega t) \) and \( m_i \omega^2 \sin(\omega t) \) are the imbalances due the difference between rotor geometric center and mass center. These imbalances cause the whirling motion and the magnitude is proportional to the rotor rotational speed, \( \omega \). The gyroscopic effect is represented by the terms \( -J_i \omega \dot{\alpha} \) and \( J_i \omega \dot{\beta} \), where it can be noticed that this will cause the coupling between the axes of motions proportional to the speed. The control forces produced by the AMB are given by the following equations:

\[ \begin{align*}
    f_{xs} & = 2K_i x_i \omega + 2L_i K_m \beta + 2K_i I_i \\
    f_{ys} & = 2K_i y_i \omega - 2L_i K_m \alpha + 2K_i I_i
\end{align*} \] (2)

where \( f_{sx} = f_{xu} - f_{xw} \) and \( f_{sy} = f_{yu} - f_{yw} \) are the net forces produced by the AMB on each x- and y-axis respectively (the same net force for bottom PMB as well). This is possible by having the AMB coil wound to produce differential current mode. For the PMB, the net forces produced are given by the following equations:

\[ \begin{align*}
    f_{xb} & = -2C_i \dot{x}_i \omega + 2C_i L_i \dot{\beta} - 2K_i x_i \omega + 2K_i L_i \beta \\
    f_{yb} & = -2C_i \dot{y}_i \omega - 2C_i L_i \dot{\alpha} - 2K_i y_i \omega - 2K_i L_i \alpha
\end{align*} \] (3)

Equations (1), (2) and (3) can be integrated to produce the AMB model in the following form:

\[ X(t) = A(\omega)X(t) + BU(t) + F(\omega,t) \] (4)

where \( X = [x_i, \beta, y_i, \alpha, \dot{x}_i, \dot{\beta}, \dot{y}_i, \dot{\alpha}]^T \) are the states of the system, \( A(\omega) \in \mathbb{R}^{8x8} \) is the system matrix, \( B \in \mathbb{R}^{8x2} \) is the input matrix, \( U(t) = [I, I, I]^T \) the input currents. The nonzero elements of the matrices are shown in the Appendix A. The range of the rotor speed is given below:

\[ 0 \text{ rpm} \leq \omega \leq 10,000 \text{ rpm} \] (5)

From the dynamic model (4), the uncertainties present in the system are in the system and disturbance matrix which are due to gyroscopic effect and mass imbalance. The parameters of the AMB system are given in Appendix C.

III. \( H_2 \)-BASED SLIDING MODE CONTROL DESIGN

Consider a class of uncertain system

\[ \dot{x}(t) = (A + \Delta A(\omega))x(t) + Bu(t) + F(\omega,t) \] (6)
where $x(t) \in \mathbb{R}^n$ is the system states, $u(t) \in \mathbb{R}^m$ is the control input and $\omega$ is any time-varying scalar function. $A$ and $B$ is the system and input matrices, respectively, and $B$ is of full rank. $\Delta A(\omega)$ represents the uncertainty in the system matrix and $E$ is the disturbance matrix that map the disturbance $w(\omega,t)$ into the system. To complete the description of the uncertain dynamical system, the following assumptions are introduced and assumed to be valid.

**A1)** The system uncertainty $\Delta A(\omega)$ and the disturbance $E$ are mismatched such that:

$$R(B) \subset R(E) + R(\Delta A)$$

**A2)** The linear model mismatch is supposed to belong to a convex polytope in parameter space such that:

$$\Delta A = \sum_{i=1}^{k} \alpha_i A_i, \quad \sum_{i=1}^{k} \alpha_i = 1, \quad \alpha_i \geq 0 \forall i \in 1, \cdots, k.$$

**A3)** The pair $(A,B)$ is controllable.

**A4)** All states are available.

The sliding surface is defined as:

$$\sigma = Cx(t) = 0 \quad \text{(7)}$$

where $C$ is the design matrix that determines the desired performance of the $(n-m)$ reduced-order closed-loop system.

Define an output variable as:

$$z(t) = Lx(t) \quad \text{(8)}$$

Due to the mismatched condition, the transfer function from the exogenous input vector $w(t)$ to this output $z(t)$ is given by

$$Z(s) = H(s)W(s) \quad \text{(9)}$$

where $Z(s)$ and $W(s)$ are the Laplace transform of $z(t)$ and $w(t)$ respectively and $H(s)$ is valid for $t > \tau$. When the system in the sliding motion, the $H_2$ norm of the transfer function (9) for the closed-loop system is defined as follows:

$$\|H(s)\|_2^2 = \frac{1}{2\pi} \int_{-\infty}^{\infty} \left| \Phi[H(j\omega)]^* H(j\omega) \right| d\omega \quad \text{(10)}$$

From this, as highlighted in [9], the main objective is to find the optimal sliding surface $C_{\text{opt}}$ such that the upper bound of the $H_2$ norm (10) over all mismatched $\Delta A$ such that:

$$C_{\text{opt}} = \arg \min_{C} \max_{\Delta A} \Omega(C, \Delta A), \quad \Omega(C, \Delta A) \geq \|H(s)\|_2 $$

The minimization of the upper bound of $\Omega(C, \Delta A)$ which can be found as the solution of the sliding surface as explained in the following section.

**A. Canonical Transformation**

The design of the sliding surface is carried by transforming the system dynamic into a regular form and this is in-line with the step outlined in [2][4]. The transformation matrix $T$ is chosen such that

$$TB = \begin{bmatrix} 0 \\ B_2 \end{bmatrix}, \quad TT^T = I \quad \text{(12)}$$

where matrix $B_2 \in \mathbb{R}^{n \times m}$ is nonsingular. Then applying this transformation to system (6), a new system representation is obtained as:

$$\bar{x} = Tx \quad \bar{x} = (A + \Delta A)T^{-1}\bar{x} + T Bu + TEw \quad \text{(13)}$$

$$CT^{-1}\bar{x} = 0 \quad \quad z = LT^{-1}\bar{x}$$

Thus, the system states can be partitioned as follows:

$$\bar{x} = \begin{bmatrix} \bar{x}_1 \\ \bar{x}_2 \end{bmatrix}, \quad \bar{x}_1 \in \mathbb{R}^{n-m}, \quad \bar{x}_2 \in \mathbb{R}^m \quad \text{(14)}$$

Then, the matrices of the system can be partitioned to form the following new matrices:

$$\bar{A} = TAT^{-1} = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}, \quad \bar{\Delta A} = T\Delta A T^{-1} = \begin{bmatrix} \Delta A_{11} & \Delta A_{12} \\ \Delta A_{21} & \Delta A_{22} \end{bmatrix}, \quad \bar{E} = TE = \begin{bmatrix} E_1 \\ E_2 \end{bmatrix}, \quad \bar{C} = CT^{-1} = \begin{bmatrix} C_1 & C_2 \end{bmatrix} \text{ and } \bar{L} = LT^{-1} = \begin{bmatrix} L_1 & L_2 \end{bmatrix} \quad \text{(15)}$$

Following the same procedure in [2], the surface equation becomes

$$\bar{C}_1\bar{x}_1 + \bar{C}_2\bar{x}_2 = 0 \quad \text{(16)}$$

By knowing that $\det(\bar{C}_2) \neq 0$, this will lead to

$$\bar{x}_2 = -\bar{C}_2^{-1}\bar{C}_1\bar{x}_1 \quad \text{(17)}$$

To simplify the derivation, the following terms are introduced which are:

$$F_{\Delta AC, \bar{C}_1}$$
From (15), (16) and these new terms, the new representation of the reduced-order closed-loop system is obtained as follows:

\[ \dot{x}_1 = \Phi \bar{x}_1 + \Gamma \bar{x}_2 + \bar{E}_1 w, \]
\[ \bar{x}_2 = -\Gamma \bar{x}_1, \]
\[ z = \bar{L}_1 \bar{x}_1 + \bar{L}_2 \bar{x}_2 \]  
(19)

Thus, viewing this closed-loop system, it is obvious that the design of the sliding surface is equivalent to designing feedback gain, \( F \), for the reduced-order system with uncertainties. Looking at the assumption A2), the matrices \( \Phi \Delta \bar{A}_{11} + \Delta \bar{A}_{12} \) and \( \Gamma \Delta \bar{A}_{21} + \Delta \bar{A}_{12} \) also belongs to a polytope-type set with known vertices. The set can be defined as follows:

\[ \rho \Delta = \left\{ (\Phi, \Gamma), \sum_{i=1}^{k} \alpha_i (\Phi_i, \Gamma_i) \sum_{i=1}^{k} \alpha_i = 1, \alpha_i \geq 0 \right\} \]  
(20)

The vertices of this polytope (20) corresponds to he vertices of the uncertain defined in A2) obtained by using the transformation matrix \( T \).

**B. \( H_2 \) Guaranteed Cost Sliding Surface Design**

By following the design step outline in [9], an assumption on the matrix \( L \) in (8) is introduced in which the assumption will guarantee that the \( H_2 \) cost function optimization for the sliding surface design is nonsingular. The assumption is as follows:

\[ \bar{L}_2 \bar{L}_2 > 0 \]  
(21)

As discussed in the next section, although for AMB system that the freedom of choosing the matrix \( L \) is quite flexible, the velocities of the gap displacements are also required to fulfill this condition and thus to avoid singularity problem in finding the solution. In practical point of view, getting the velocities of the gap is expensive and may cause some constraints. In this work, however, only the theoretical aspect is concerned and as imposed by assumption A4) this requirement has not put any limitation in obtaining the final result.

Then, with this assumption (21), a new variable is introduced as follows:

\[ e(t) = (\bar{L}_2 \bar{L}_2)^{-1} \bar{L}_2 \bar{x}_2 + \bar{x}_2 \]  
(22)

The reduced-order system (19) may be written in term of \( \bar{x}_1 \) and \( e \) as

\[ \dot{\bar{x}}_1 = (\Phi - \Gamma (\bar{L}_2 \bar{L}_2)^{-1} \bar{L}_2 \bar{L}_2) \bar{x}_1 + \Gamma e + \bar{E}_1 w \]

Furthermore, the system can be simplified by defining the following terms:

\[ \bar{\Phi} = \Phi - \Gamma (\bar{L}_2 \bar{L}_2)^{-1} \bar{L}_2 \bar{L}_2 \]
\[ \bar{\Gamma} = \bar{L}_2 (\bar{L}_2 \bar{L}_2)^{-1} \bar{L}_2 \bar{L}_2 \]  
(24)

Then, the transformed uncertainty polytope (20) can be recast as:

\[ (\bar{\Phi}, \bar{\Gamma}) \in \rho \iff (\Phi, \Gamma) \in \rho \]
\[ \bar{\Phi}_i = \Phi_i - \Gamma_i (\bar{L}_2 \bar{L}_2)^{-1} \bar{L}_2 \bar{L}_2, \forall i = 1, \ldots, k \]  
(25)

From (19) and (22), the transformed gain matrix is

\[ e(t) = (-F + (\bar{L}_2 \bar{L}_2)^{-1} \bar{L}_2 \bar{L}_2) \bar{x}_1 = K \bar{x}_1 \]  
(26)

Consider now the set \( \Xi \) of the symmetric positive-definite matrices \( X \) such that:

\[ \Xi: \{ X \in \mathbb{R}^{(n-m)\times(n-m)} | X = X^T > 0; \}
\[ (\bar{\Phi} - \Gamma K)X + X(\bar{\Phi} - \Gamma K)^T + \bar{E}_1 \bar{E}_1 \leq 0, \forall (\bar{\Phi}, \bar{\Gamma}) \in \rho \} \]  
(27)

For an arbitrary but fixed pair of \( (\bar{\Phi}, \bar{\Gamma}) \in \rho \), the \( H_2 \) norm of system (23) is bounded by:

\[ \| H(s) \|_2 \leq tr((\Lambda - \bar{L}_2 \bar{L}_2)X(\Lambda - \bar{L}_2 \bar{L}_2)^T), \forall X \in \Xi. \]  
(28)

Let a new matrix \( W \in \Xi \), then a new variable can be defined as

\[ Z = KW, \quad K = ZW^{-1} \]  
(29)

Thus, the problem of minimization of the upper bound of the \( H_2 \) norm (28) can be represented as

\[ \min tr(\Lambda WX^T + \bar{L}_2 ZW^{-1}Z^T \bar{L}_2^T) \]
\[ s. t.: \quad \Xi W - \Gamma Z + W Z^T - Z \Gamma^T + \bar{E}_1 \bar{E}_1 \bar{E}_1^T \leq 0, \forall (\bar{\Phi}, \bar{\Gamma}) \in \rho. \]  
(30)

Obviously, this problem can be expressed as LMI problem [12]. Defining the objective function in (30) as a new variable as follows:

\[ Q \geq \Lambda WX^T + \bar{L}_2 ZW^{-1}Z^T \bar{L}_2^T \]  
(31)

Taking the Schur complement of (31), then, the problem can be represented as LMI optimization problem:

\[ \Omega^2 = \min_{W,Z,Q} tr(Q) \]

\[ \Xi: \{ X \in \mathbb{R}^{(n-m)\times(n-m)} | X = X^T > 0; \}
\[ (\bar{\Phi} - \Gamma K)X + X(\bar{\Phi} - \Gamma K)^T + \bar{E}_1 \bar{E}_1 \leq 0, \forall (\bar{\Phi}, \bar{\Gamma}) \in \rho \} \]  
(27)

For an arbitrary but fixed pair of \( (\bar{\Phi}, \bar{\Gamma}) \in \rho \), the \( H_2 \) norm of system (23) is bounded by:

\[ \| H(s) \|_2 \leq tr((\Lambda - \bar{L}_2 \bar{L}_2)X(\Lambda - \bar{L}_2 \bar{L}_2)^T), \forall X \in \Xi. \]  
(28)

Let a new matrix \( W \in \Xi \), then a new variable can be defined as

\[ Z = KW, \quad K = ZW^{-1} \]  
(29)

Thus, the problem of minimization of the upper bound of the \( H_2 \) norm (28) can be represented as

\[ \min tr(\Lambda WX^T + \bar{L}_2 ZW^{-1}Z^T \bar{L}_2^T) \]
\[ s. t.: \quad \Xi W - \Gamma Z + W Z^T - Z \Gamma^T + \bar{E}_1 \bar{E}_1 \bar{E}_1^T \leq 0, \forall (\bar{\Phi}, \bar{\Gamma}) \in \rho. \]  
(30)

Obviously, this problem can be expressed as LMI problem [12]. Defining the objective function in (30) as a new variable as follows:

\[ Q \geq \Lambda WX^T + \bar{L}_2 ZW^{-1}Z^T \bar{L}_2^T \]  
(31)

Taking the Schur complement of (31), then, the problem can be represented as LMI optimization problem:

\[ \Omega^2 = \min_{W,Z,Q} tr(Q) \]
If the solution of (32) is feasible, then Theorem 1 in [9] hold and the sliding surface parameter that guarantees the existence of the optimal upper bound $H_2$ norm can be obtained. With the values of $W$ and $Z$ determined, as stated in the theorem, the gain $K$ in (29) can be obtained and lead to the optimal surface values as follows:

$$C_{opt} = \begin{bmatrix} \overline{C}_1 \left( (\overline{T}_2^T \overline{L}_2)^{-1} \overline{T}_2^T \overline{T}_1 - K \right) \overline{C}_2 \end{bmatrix}^T$$

(33)

Notice that the matrix $\overline{C}_2$ does not have any influence in the reduced order system and can be chosen freely provided it is full rank and $\overline{C}_2 = I$ is a convenient as stated in [2][4][9].

### C. Control Law

The next phase in the design phase of sliding mode control is to propose a control law that can ensure the reachability condition is met. For this work, the control law in [2] is adapted as follows:

$$u(t) = -(CB)^{-1}CAx(t) - \rho \text{sign}(Cx(t))$$

(34)

where $\rho$ is any small positive constant to bound matched uncertainties. The proof of the reachability condition can be found in [2] and purposely not shown here.

### IV. SIMULATION ON AMB SYSTEM AND DISCUSSION

The simulation work is performed by using MATLAB® and Simulink®. For solving the LMI problem (32), instead of using standard LMI Toolbox in Matlab, YALMIP/SeDuMi convex problem solver for semi-definite problem is used [13][14]. YALMIP/SeDuMi is among the newly developed convex problem solver which is proven to produce a less conservative solution and a higher convergence rate. The procedure of designing the sliding surface of the controller and its application on the AMB system is outlined as follows:

**Step 1:** Choose the output matrix $L$. For this work two output matrix $L$ are chosen as follows:

$$L_s = \begin{bmatrix} 1 & 1 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 1 & 0 & 0 & 1 & 0 \end{bmatrix},$$

The reason to choose two output matrices is to demonstrate how the performance of the controller is significantly affected by the structure of $L$. Specifically for this AMB system, the practically desired outputs can be obtained by linear combination of the system states in which this provides great freedom to choose the structure of matrix $L$. Thus, both of these matrices are valid for this system as long as the assumption that all the states are available is valid.

**Step 2:** Obtain the orthonormal transformation matrix using QR decomposition which is as follows:

$$T = \begin{bmatrix} 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ -0.1844 & 0 & 0 & 0.9660 & -0.1812 & 0 & 0 & 0 \\ -0.9829 & 0 & 0 & -0.1812 & 0.0340 & 0 & 0 & 0 \\ 0 & -0.1844 & 0 & 0 & 0 & 0.9660 & 0.1812 & 0 \\ 0 & 0.9829 & 0 & 0 & 0 & 0.1812 & 0.0340 & 0 \\ 0 & 0 & 0 & -0.1844 & -0.9829 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & -0.1844 & 0.9829 \end{bmatrix}$$

Note that the transformation matrix is not unique. As outlined previously the chosen $T$ must fulfill the requirement (12).

**Step 3:** Transform the system into regular form and find the matrices $\Phi_1, \Phi_2, \Gamma_1, \Gamma_2, \overline{\Phi}_1, \overline{\Phi}_2$ and $\Lambda$.

After performing the transformation into reduced-order system, the set of matrices using each $L_s$ and $L_b$ are obtained. Due to page limitation, only the matrices obtained from $L_s$ are included in this paper. The matrices that belong to $L_s$ can be obtained in the same manner. The matrices for $L_s$ are shown in Appendix B.

**Step 4:** Solve LMI set (32) for $K$ and $C_{opt}$ from (33). By using the YALMIP/SeDuMi LMI solver, the calculated parameters are as follows:

$$K = \begin{bmatrix} -2.7145 & 0.0031 & -0.0329 & -0.1753 & 0.0032 & -0.0170 \\ 88.7157 & -0.0405 & 0.1228 & 0.6545 & -0.0251 & 0.1278 \end{bmatrix}$$

$$C = \begin{bmatrix} -5.6019 & -5.4063 & 2.7145 & -0.0031 & -5.4236 & 0 \\ 0.6659 & -0.1302 & -94.1392 & 5.3830 & 0 & 0 \\ 0 & 0 & -5.4224 & 0.0002 \end{bmatrix}$$
With this C matrix available, by using the control law (34), the complete closed-loop system can be simulated. The initial values of the states are set at $[x_1, \beta_1, y_1, \alpha_1, x_2, \beta_2, y_2, \alpha_2]^T = [8 \times 10^{-6}, 0, 20 \times 10^{-6}, 0, 0, 0, 0, 0]^T$. The system is run at two rotor speeds which are 6000 rpm and 10000rpm. As highlighted in [8], the high resonant speed occurs at 6000 rpm in which the radius of the whirling motion of the rotor is the biggest. The value $\rho = 0.8$ is selected for all simulation work. As a comparison, the result obtained in [8] as shown in Fig. 3 is used for benchmarking in which the rotor orbit is about 95 micron in diameter.

When the rotor speed is set at $\omega = 6000$rpm, Fig. 4 shows the trajectories of the states $X$ and $Y$ and the rotor orbit when the output matrix $L_1$ is used. It can be seen that the system is approaching asymptotic stability and almost not whirling motion occurs at steady state. When the output matrix is $L_0$ chosen, the rotor orbit of about 12 micron is produced at steady state as shown in Fig. 5. This is a reduction of 87% of the trajectories of the states constrained by the designed surface.

To further assess the performance of the system, Fig. 6 shows the trajectories of $X$ and $Y$ and the rotor orbit with $L_1$ and rotor speed of $\omega = 10000$ rpm. It can be noticed that the system response is almost similar to the response when running at $\omega = 6000$ rpm in which the system is approach zero diameter of rotor orbit. For the surface parameter with $L_1$, the system response is shown in Fig. 7 where the rotor orbit is about 30 micron. This demonstrates that with the present of the mismatched uncertainties and disturbance, the system response still achieves at the worst the bounded stability as constrained by the designed surface.

The sliding surfaces $\sigma_1$ and $\sigma_2$ are shown in Fig. 8 where both surfaces are maintaining at the neighbourhood of ideal sliding surface, $\sigma = 0$. The non-smooth sliding motion is due to the present of the mismatched uncertainties and the imbalance of the AMB system in which this mismatched effect has forced the system to slide off the ideal sliding surface and remain in the designed sliding surface. The control current $I_x$ and $I_y$ is shown in Fig. 9 in which the chattering effect is due to the signum function in the control.
law. There are many methods reported to eliminate the chattering effect, however, it is insignificant in this work and purposely not covered.

V. CONCLUSION

In this work, an application of a SMC controller with $H_2$ guaranteed cost switching function into AMB system is performed. The proposed controller is proven to be able to achieve the proposed $H_2$ norm bounded stability at a wide range of rotational rotor speed although with the present of mismatched and matched system uncertainty. The performance of the controller is demonstrated through various simulation works.

APPENDIX A

The nonzero elements of matrix $A(o,t)$, $B$ where $i$ and $j$ indicate the $i$-th and $j$-th entry of each element.

$$a_{i1} = \frac{2(K_m - K_s)}{m}, a_{i2} = \frac{2(L_m K_m - L_s K_s)}{m}, a_{i3} = \frac{2C_m}{m}, a_{i4} = \frac{2C_s}{m},$$

$$a_{i5} = \frac{2L_m C_m - L_s C_s}{J_r}, a_{i6} = \frac{2(L_m K_m + L_s K_s)}{m}, a_{i7} = \frac{2J_m C_m}{J_r}, a_{i8} = \frac{2(L_m K_m - L_s K_s)}{m},$$

$$f_i = m\omega^2\cos(\omega t), f_j = m\omega^2\sin(\omega t).$$

APPENDIX B

Elements of matrices $\Phi_1, \Phi_2, \Gamma_1, \Gamma_2, \Phi_3, \Phi_4$ and $A$ for $L_r$.

$$\Phi_1 = 10^3 \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1.6930 & 9.0314 & -0.1427 & 0.7614 \\ 0 & 0 & -0.3176 & -1.6943 & 0.0268 & -0.1428 \\ -9.1888 & -0.7746 & -0.0001 & 0 & -0.0043 & -0.0008 \\ -1.7238 & -0.1453 & 0 & 0 & -0.0008 & -0.0002 \end{bmatrix}$$

$$\Phi_2 = 10^3 \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1.6930 & 9.0314 & -0.1425 & 0.7614 \\ 0 & 0 & -0.3176 & -1.6943 & 0.0267 & -0.1428 \\ -9.1888 & -0.7746 & -0.0003 & 0.0001 & -0.0043 & -0.0008 \\ -1.7238 & -0.1453 & -0.0001 & 0 & -0.0008 & -0.0002 \end{bmatrix}$$

$$\Gamma_1 = \begin{bmatrix} -15.0694 & 78.3917 \\ 3.0146 & -14.7061 \\ -78.2104 & 44.7795 \\ -15.6721 & 8.4005 \end{bmatrix}, \Gamma_2 = \begin{bmatrix} -0.1844 & 0.9829 \\ 0.9829 & 0.1844 \\ 3.0146 & -29.41221 \\ -156.60214 & 44.7795 \\ -30.37821 & 8.4005 \end{bmatrix}.$$
ACKNOWLEDGMENT

The financial support by Ministry of Science, Technology and Innovation, Malaysia (MOSTI) and Universiti Teknologi Malaysia (UTM) under the E-Science fund under Vot. No. 79014 managed by Research Management Unit (RMC) is acknowledged. A. R. Husain also would like to thank Didier Henrion (LAAS-CNRS, Toulouse) for introducing YALMIL/SeDuMi LMI solver.

APPENDIX C

### TABLE I

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Parameter for AMB system [8]</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Value</td>
</tr>
<tr>
<td>( m )</td>
<td>Mass of Rotor</td>
</tr>
<tr>
