Mercerization Treatment Parameter Effect on Natural Fiber Reinforced Polymer Matrix Composite: A Brief Review

Mohd Yussni Hashim, Mohd Nazrul Roslan, Azriszul Mohd Amin, Ahmad Mujahid Ahmad Zaidi and Saparudin Ariffin

Abstract—Environmental awareness and depletion of the petroleum resources are among vital factors that motivate a number of researchers to explore the potential of using natural fiber as an alternative composite material in industries such as packaging, automotive and building constructions. Natural fibers are available in abundance, low cost, lightweight polymer composite and most importantly its biodegradability features, which often called “eco-friendly” materials. However, their applications are still limited due to several factors like moisture absorption, poor wettability and large scattering in mechanical properties. Among the main challenges on natural fibers reinforced matrixes composite is their inclination to entangle and form fibrils during processing due to fiber-fiber interaction. This tends to prevent better dispersion of the fibers into the matrix, resulting in poor interfacial adhesion between the hydrophobic matrix and the hydrophilic reinforced natural fiber. Therefore, to overcome this challenge, fiber treatment process is one common alternative that can be used to modify the fiber surface topology by chemically, physically or mechanically technique. Nevertheless, this paper attempt to focus on the effect of mercerization treatment on mechanical properties enhancement of natural fiber reinforced composite or so-called bio composite. It specifically discussed on mercerization parameters, and natural fiber reinforced composite mechanical properties enhancement.

Keywords—Mercerization treatment, mechanical properties, natural fiber and bio composite

I. INTRODUCTION

The use of natural fibers as reinforced material in composite manufacturing was incredibly increased due to environmental awareness, depletion of non-renewable petroleum resource and growing demand on sustainable product development [1-3]. A tremendous number of publications over the past two decades have agreed that natural fibers give competent potential to be used as an alternate for glass or other’s man made synthetic fiber reinforcement materials in composites [4-9].

Mohd Yussni Hashim, Mohd Nazrul Roslan and Azriszul Mohd Amin are with the Department of Mechanical Engineering Technology, Faculty of Mechanical & Manufacturing Engineering, Universiti Tun Hussein Onn Malaysia, 86400 Parit Raja, Batu Pahat, Johor, Malaysia. (corresponding author to provide phone: 6013-7795230; fax: 607-4536080; e-mail: yusni@uthm.edu.my).

Ahmad Mujahid Ahmad Zaidi is with Department of Mechanical Engineering, Faculty of Engineering, National Defense University of Malaysia, Kuala Lumpur, Malaysia (e-mail: mujahid@upnm.edu.my).

Saparudin Ariffin is with the Research, Innovation, Commercialization & Consultancy Office, Universiti Tun Hussein Onn Malaysia, Johor, Malaysia. (e-mail: sapar@uthm.edu.my).

The applications is diversified into the engineering end uses mainly for non structural applications such as in interior lining for automotive component [10-11], packaging materials [12], insulation [13-14], acoustic absorption panel [15-16] and building materials [17-18]. These eco friendly materials have various interesting properties, which make it an attractive and comparable to traditional synthetic reinforced material. Some of natural fiber advantages are abundantly available, inexpensive, low density, high specific stiffness and strength, lightweight, desirable fiber aspect ratio, minimal health hazards, non-abrasive, outstanding insulation properties, enhanced energy recovery, renewability and biodegradability [19-22]. However, although natural fiber reinforced composite seem to give a promising benefit as compare to synthetic fiber, there are still several critical issues need to be addressed before manufacturing industry gains full confidence to enable wide-scale acceptance of this material in a global market. The shape, size and strength of the natural plant fibers may vary widely depending on cultivation environment, geographical origin, plant maturity, retting technique, and composite manufacturing process [23-24].

The numerous highlight problem in dealing with natural fiber was it hydrophilic nature, which leads to an adhesion problem with hydrophobic nature of the polymer matrix [23]. Hydrophilic character of natural fibers is incompatible with hydrophobic polymer matrix and has a tendency to form aggregates. Furthermore, it exhibit poor resistant to moisture, which lead to high water absorption, subsequently resulting in poor mechanical properties and dimensional stability of the natural fiber reinforced composites [24-25]. Therefore, chemical modifications either on natural fiber, polymer matrix or both materials are an alternative solution to overcome these challenges [26-30]. The chemical modification is attempted to improve natural fiber hydrophobic nature, interfacial bonding between matrix and fiber, surface roughness and wettability, and also decrease moisture absorption, leading to the enhancement of mechanical properties of the natural fiber reinforced composites [8, 31]. Mercerization is a common fiber treatment that extensively used by the number of researcher [32-35]. However, for various types of fiber, distinct mercerization treatment conditions were used, and very limited paper took a partial review on these condition interaction effects on fiber and it composite properties enhancement.
Thus, the aim of this paper is to briefly review the mercerization parameter's effect on natural fiber and its composite mechanical properties enhancement. The mercerization parameters that will be stress in this paper are sodium hydroxide (NaOH) concentration, temperature and soaking duration. This paper also attempts to discuss the interaction of mercerization parameter's interaction toward mechanical properties enhancement of natural fiber reinforced composite. The next section of this paper will briefly describe the mercerization treatment. Section three discussed the common mercerization treatment conditions. The following section is about properties enhancement via mercerization treatment. The conclusion of this work and the recommendation for future work will be highlighted at conclusion section.

II. MERCERIZATION TREATMENT

Mercerization is an alkali treatment process. It is widely used in textile industry [36]. The standard definition of mercerization as proposed by ASTM D1965 is: the process of subjecting a vegetable fiber to an interaction with a fairly concentrated aqueous solution of strong base, to produce great swelling with resultant changes in the fine structure, dimension, morphology and mechanical properties [1]. Therefore, mercerization is a chemical modification process that changed the chemical constituent behavior in natural fiber. The effect of alkali on cellulose fiber is a swelling reaction, during which the natural crystalline structure of the cellulose relaxes. The schematic illustration of the swelling process in cellulose is shown in Fig. 1 [37]. Native cellulose (i.e. cellulose as it occurs in nature) shows a monoclinic crystalline lattice of cellulose-I, which can be changed into different polymorphous forms through chemical or thermal treatments. The important forms of alkali-cellulose and cellulose-II are shown in Fig. 2 [21].

The type of alkali and its concentration will influence the degree of swelling, and hence the degree of lattice transformation into cellulose-II. It has been reported that Na+ has got a favorable diameter, able to widen the smallest pores in between the lattice planes and penetrate into them. Consequently, sodium hydroxide (NaOH) treatment results in a higher amount of swelling. This leads to the formation of new Na–cellulose-I lattice, a lattice with relatively large distances between the cellulose molecules, and these spaces are filled with H2O molecules. In this structure, the OH-groups of the cellulose are converted into O–Na-groups, expanding the dimensions of molecules. Subsequent rinsing with water will remove the linked Na-ions and convert the cellulose to a new crystalline structure, i.e. cellulose-II, which is thermodynamically more stable than cellulose-I. NaOH can cause a complete lattice transformation from cellulose-I to cellulose-II. Addition of aqueous sodium hydroxide (NaOH) to natural fiber promotes the ionization of the hydroxyl group to the alkoxide. The following reaction takes place as a result of alkali treatment [26, 37-38]:

Fiber – OH + NaOH → Fiber – O– Na + H2O      (1)

As reported in much literature, natural fiber chemical constituent consists of cellulose and other non cellulosic constituent like hemicellulose, lignin, pectin and impurities such as wax, ash and natural oil [39-40]. This non cellulose material could be removed by appropriate alkali treatments, which affect the tensile characteristic of the fiber [38, 41]. Mercerization was found to change fiber surface topography, and the fiber diameter was reported to be decreased with increased concentration of sodium hydroxide concentration [42]. Mercerization treatment also results in surface modifications leading to increase wettability of coir fiber polyester resin as reported by Prasad et. al [43]. It is reported in that alkaline treatment has two effects on the henequen fiber: (1) it increases surface roughness, resulting in better mechanical interlocking; and (2) it increases the amount of cellulose exposed on the fiber surface, thus increasing the number of possible reaction sites [44]. Consequently, alkaline treatment has a lasting effect on the mechanical behavior of natural fibers, especially on their strength and stiffness.

III. TREATMENT CONDITIONS

An excellent discussion of mercerization effects and its observed behavior was reported by Symington et al [45]. They highlight two important mercerization treatments, which are NaOH concentration and processing time could increase 30% in interfacial strength in composite with a proper pretreatment process. The general concentration ranges of NaOH seem to be 1-25% and processing time of 1-60 minute.

However, in real application, due to chemical constituent variation among similar types or different types of natural fiber, optimal mercerization conditions like NaOH concentration, time and temperature will vary for each fiber. Norazawa et al study the effect of alkali treatment on kenaf – Ecoflex composites mechanical properties. The composite was prepared to use different fiber loading, and the fiber was treated with various concentrations of NaOH solution. They're found that 40% fiber loading improved the tensile strength of the composite.

properties and whole stem kenaf fiber treated with 4% NaOH was found to enhance composite tensile and flexural properties compared with untreated fiber [56]. Umar et al. reported that 4% NaOH could clean the impurities and make a Betelnut fiber surface a bit rougher [57]. When NaOH concentration increased to 6%, they found that Betelnut fiber became totally free from any impurities.

Table I expressed a literature summary stress on mercerization treatment parameters focused on NaOH concentration, processing temperature and soaking duration. From Table 1, it shows a number of researches were conducted to determine the optimum NaOH solution concentration during the mercerization process at specific soaking duration and/or soaking temperature. However, there are limited work reported regarding attempts to determine the main effect and the interaction between these three factors on it effect to natural fiber and its final composite mechanical properties performance.

**IV. PROPERTIES ENHANCEMENT**

When dealing with natural fiber reinforce composite, generally there will have two stages of performance evaluation. First, is the natural fiber characteristic evaluation [58-59] and secondly is the fabricated composite evaluation [60]. Most of the literature were focused on both stages which considering some modification on the fiber [61] or polymer matrix [62] and finally evaluate the final composite performance which generally fabricated with variation of fiber matrix mixing ratio. There are tremendous research conducted to evaluate performance of natural fiber and it reinforced composite [18, 21, 23, 63-65]. This performance evaluation is mostly depending on composite characterization determination and presented in terms of physical, mechanical and thermal properties. These characteristics are important to determine material ability, especially under extreme and critical conditions, which are directly connected with engineering performance.

These characteristics are important to determine material ability, especially under extreme and critical conditions, which are directly connected with engineering performance. In this short review, the focused was zoomed in mercerization parameters effect on natural fiber physical properties and its reinforced composite mechanical properties. The mercerization effect on common mechanical properties of several natural fibers and it composite commonly was highlight in Table 2. Table 2 highlighted the properties of natural fiber and it fiber reinforced polymer composite. In fiber stage, the stressed properties were fiber-matrix interfacial shear strength and fiber tensile properties. For composite stage, the mechanical properties like tensile strength, flexural strength and impact strength was reviewed.

V. CONCLUSIONS

This review paper has considered significant used of the mercerization treatment process in natural fiber reinforced polymer matrix composite. The text addressed the mercerization parameters (sodium hydroxide (NaOH) concentration, temperature and soaking duration) effect on properties enhancement of it composite. However, due to the large variety in natural fiber types which effect it chemical composition, the treatment condition also found to be different according to the selected reinforced fiber. As a conclusion from this brief review, the following issues could be highlighted for further understanding the mercerization treatment conditions effect on natural fiber reinforced polymer composite mechanical properties enhancement.
Mercerization or alkali treatment is one of the common techniques that widely used for modification of fiber surface. Furthermore, this treatment was considered as a simplest and cheapest treatment method compared to other chemical treatment methods.

In this brief review, it was clearly shown that although tremendous research results were published regarding natural fiber mercerization treatment, there are still scant works conducted in dealing with interaction and optimizing the mercerization treatment conditions.

It was found that the most parameters used in mercerization treatment were alkali concentration, fiber soaking temperature and fiber soaking duration. Although similar types of reinforced fiber are used, it could give different values in its final composite mechanical properties due to different parameter setting during a mercerization treatment process.

Therefore, there is a significant need to conduct further work focusing on main effect and interaction effect of mercerization parameters setting toward enhancement of natural fiber reinforce composite mechanical properties.
