

# Coverage Availability for the IEEE 802.16 System over the SUI Channels with Rayleigh Fading

Shiann-Shiun Jeng, #Chen-Wan Tsung, Hong-You Liou, Chun-Chieh Chang, and Jia-Ming Chen

**Abstract**—The coverage probability and range of IEEE 802.16 systems depend on different wireless scenarios. Evaluating the performance of IEEE 802.16 systems over Stanford University Interim (SUI) channels is suggested by IEEE 802.16 specifications. In order to derive an effective method for forecasting the coverage probability and range, this study uses the SUI channel model to analyze the coverage probability with Rayleigh fading for an IEEE 802.16 system. The BER of the IEEE 802.16 system is shown in the simulation results. Then, the maximum allowed path loss can be calculated and substituted into the coverage analysis. Therefore, simulation results show the coverage range with and without Rayleigh fading.

**Keywords**—OFDM, coverage, SUI channel, IEEE 802.16

## I. INTRODUCTION

ORTHOGONAL frequency division multiplexing (OFDM) is the most popular wireless communication technique in recent years and adapted in IEEE specifications, e.g. 802.11 and 802.16 serial standards. The coverage range of the 802.11 system is restricted within approximately 100 m. Therefore, the IEEE 802.16 serial standards have been proposed to solve this problem. The IEEE 802.16 system has not only a higher data rate but also a wider transmission range; the maximum data rate may achieve 75 Mbps and the maximum coverage range may achieve 50 km [1]. However, in reality, the coverage range and probability vary with different wireless environments for an IEEE 802.16 system. Thus, evaluating IEEE 802.16 system coverage probability and transmission range before constructing a base station is extremely important. In [2], the coverage of the IEEE 802.16 system was predicted for several channel models using different modulation schemes. In [3], the IEEE 802.16 system performance, including transmission range, was analyzed. In [4], the coverage analysis for WiMAX systems was presented by using the free space propagation model.

In [5], the coverage analysis of the IEEE 802.16d system over the Stanford University Interim (SUI) channel was studied and applied by the smart antenna system. IEEE 802.16 specifications propose that the SUI channel model [6] is suitable for evaluating the performance of IEEE 802.16 systems. In this paper, the performance of the IEEE 802.16 system is evaluated by utilizing the SUI channel model. This work also applies Rayleigh fading to the path loss model of the SUI channel and analyzes the coverage availability. Simulation results show the coverage probability with Rayleigh fading over the SUI channels.

The remainder of this paper is organized as follows. Section II introduces the SUI channel model and presents the basic analysis of the coverage probability. Section III proposes the coverage probability with Rayleigh fading. Section IV presents the simulation results for the performance evaluation and the coverage availability. Finally, the conclusion of this work is drawn in Section V.

## II. PRELIMINARY

### A. The Description of SUI Channels

For the SUI channel model [6], a set of six typical channels is selected for three terrain types and described as follows. For Terrain type A, SUI-5 and SUI-6 channels are hilly terrain with moderate-to-heavy tree densities. For Terrain type B, SUI-3 and SUI-4 channels are hilly terrain with light tree densities or flat terrain with moderate-to-heavy tree densities. For Terrain type C, SUI-1 and SUI-2 channels are flat terrain with light tree densities. The basic path loss equation of the SUI channel model is

$$\overline{PL}(r) = A + 10\gamma \log_{10} \left( \frac{r}{r_0} \right) + X_f + X_h + s \quad (1)$$

where  $r$  is the distance (m) between a transmitter and receiver, and  $r_0$  is the reference distance (m). In this work,  $r_0$  is 100 m, and  $r$  has to be larger than  $r_0$ .  $A$  can be represented as

$$A = 20 \log_{10} \left( \frac{4\pi r_0}{\lambda} \right) \quad (2)$$

where  $\lambda$  is the wavelength of the propagation wave.  $\gamma$  is a random variable that can be represented as

ssjeng@mail.ndhu.edu.tw, #cwtsung@mail.stu.edu.tw,  
m9623053@ems.ndhu.edu.tw, m9823022@ems.ndhu.edu.tw and  
d9323005@ems.ndhu.edu.tw

$$\gamma = a + bh_b + \frac{c}{h_b} + x\sigma_\gamma \quad (3)$$

where  $h_b$  is base-station antenna height and between 10 m and 80 m. The values of  $a$ ,  $b$ ,  $c$  and  $\sigma_\gamma$  depend on the scenarios and are shown in Table 1, and  $x$  is a Gaussian random variable with a zero mean and unit variance.

In (1), the terms  $X_f$  and  $X_h$  are modified factors for the receiver antenna frequency and height, respectively. Notably,  $X_f$  and  $X_h$  are defined as

$$X_f = 6 \log \left( \frac{f}{2000} \right) \quad (4)$$

and

$$X_h = -10.8 \log \left( \frac{h_r}{2.0} \right) \quad \text{for Terrain Types A and B} \quad (5)$$

$$X_h = -20.0 \log \left( \frac{h_r}{2.0} \right) \quad \text{for Terrain Type C}$$

where  $f$  is receiver antenna frequency (MHz) and  $h_r$  is receiver antenna height and between 2 m and 10 m.

In (1),  $s$  is a lognormal-distributed path loss factor that accounts for shadow fading caused by trees and terrain structures. In [6], the standard deviation of  $s$ , which depends on terrain type, is typically 8.2–10.6 dB. Additionally,  $s$  can be represented as a zero mean Gaussian random variable.

$$s = y\sigma \quad (6)$$

where  $y$  is a Gaussian random variable with a zero mean and unit variance. In [7], variability  $\sigma$  depends on different environments, e.g., suburban or urban environments. Thus,  $\sigma$  can be represented as

$$\sigma = \mu_\sigma + z\sigma_\sigma \quad (7)$$

where  $\mu_\sigma$  is the mean of  $\sigma$ ,  $\sigma_\sigma$  is the standard deviation of  $\sigma$ , and  $z$  is a Gaussian random variable with a zero mean and unit variance. Table 1 shows the values of  $\mu_\sigma$  and  $\sigma_\sigma$ . Therefore,  $s$  can be represented as a Gaussian random variable with a zero mean and variance  $\mu_\sigma^2$ .

### B. Coverage Probability Analysis

After describing the path loss model of SUI channel model, this study analyzes the coverage probability of an IEEE 802.16 system over SUI channels. Fig. 1 shows a cell coverage area. Assume that  $\Delta r$  approaches 0. For any variable  $r$ , the average coverage probability of the IEEE 802.16 system [7],  $P_{cell}$ , can be represented as

TABLE I PARAMETERS OF THE SUI CHANNEL MODEL

Model Parameters	Terrain A	Terrain B	Terrain C
$a$	4.6	4	3.6
$b$	0.0075	0.0065	0.005
$c$	12.6	17.1	20
$\sigma_\gamma$	0.57	0.75	0.59
$\mu_\sigma$	10.6	9.6	8.2
$\sigma_\sigma$	2.3	3.0	1.6

Fig.1 Cell coverage area for probability analysis

$$P_{cell} = \frac{1}{\pi r_{max}^2} \int_{r=0}^{r_{max}} P_e(r) \times 2\pi r dr \quad (9)$$

where  $r_{max}$  is the maximum transmission range of the IEEE 802.16 system and  $P_e(r)$  is the probability of the path loss below the threshold value at distance  $r$  and described clearly in Sec. III.

### III. THE ANALYSIS OF COVERAGE PROBABILITY WITH RAYLEIGH FADING

For the SUI channel model, the path loss model without Rayleigh fading is described in Sec. II-A. In this section, Rayleigh fading is added on the path loss model of the SUI channel model, and then the analysis of the coverage probability is presented. Therefore, the new path loss model with Rayleigh fading can be represented as

$$PL(r) = A + 10\gamma \log_{10} \left( \frac{r}{r_0} \right) + X_f + X_h + s + R \quad (10)$$

where  $R$  is Rayleigh fading factor and has a log-Rayleigh distribution. If path loss ( $PL(\cdot)$ ) is less than the path loss threshold ( $L_{th}$ ) at distance  $r$ , the probability of coverage fraction,  $P_e(r)$ , can be expressed as

$$P_e(r) = P(PL(r) < L_{th}) \quad (11)$$

where  $L_{th}$  can be represented as

$$L_{th} = (P_t + G_t) - S_r \quad (12)$$

where  $P_t$  is transmission power and  $G_t$  is antenna gain at the transmitter.  $S_r$  is the minimum input level sensitivity of the receiver [8] and can be represented as

$$S_r = -102 + SNR_r + 10 \cdot \log \left( f_s \cdot \frac{N_{used}}{N_{FFT}} \cdot \frac{N_{sch}}{16} \right) \quad (13)$$

where  $SNR_r$  is the SNR (dB) at the receiver when the BER reaches the threshold value;  $N_{sch}$  is the number of allocated subchannels (the default number of subchannels with no subchannelization is 16);  $N_{used}$  is the number of subcarriers; and  $N_{FFT}$  is the FFT size.  $f_s$  is the sampling frequency (MHz). Then, (10) is substituted to (11), and the probability of coverage fraction can be rewritten as

$$P_e(r) = P(PL(r) < L_{th}) \\ = P \left( A + 10\gamma \log_{10} \left( \frac{r}{r_0} \right) + X_f + X_h + s + R < L_{th} \right) \quad (14)$$

Assuming  $B=10\log_{10}(r/r_0)$ , (14) can be rewritten as

$$P_e(r) = P(B\gamma + s + R < L_{th} - (A + X_f + X_h)) \quad (15)$$

Let  $D$  be  $L_{th} - (A + X_f + X_h)$ . Then, the probability is represented as

$$P_e(r) = P(B\gamma + s + R < D) \\ = \iiint_{B\gamma+s+R<D} f(s) ds f(B\gamma) d\gamma f(R) dR \quad (16) \\ = \int_{-\infty}^{\infty} f(v) \int_{-\infty}^{D-v} f(s) \int_{-\infty}^{D-v-s} f(R) dR \cdot ds \cdot dv$$

where the distribution of  $R$  can be represented as

$$f(R) = \frac{10^{R/20}}{\sigma_R^2} e^{-\left(10^{R/20}\right)^2 / 2\sigma_R^2}, \quad (17)$$

where  $\sigma_R^2$  is the variance of the random variable  $R$ . The distribution of  $s$  in (16) can be represented as

$$f(s) = \frac{1}{\sqrt{2\pi}\mu_\sigma} \exp \left( -\frac{s^2}{2\mu_\sigma^2} \right) \quad (18)$$

where  $\mu_\sigma^2$  is the variance of the random variable  $s$ . The distribution of  $B\gamma$  in (16) can be represented as

$$f(B\gamma) = \frac{1}{\sqrt{2\pi}B\sigma_\gamma} \exp \left( -\left[ B\gamma - B \left( a - bh_b + \frac{c}{h_b} \right) \right]^2 / 2B\sigma_\gamma^2 \right) \quad (19)$$

where  $B(a-bh_b+c/h_b)$  is the mean of the random variable  $B\gamma$  and  $B\sigma_\gamma^2$  is the variable of the random variable  $B\gamma$ . Substituting (16) into (9), the average coverage probability with Rayleigh fading can be represented as

$$P_{cell} = \frac{1}{\pi r_{max}^2} \int_{r=0}^{r_{max}} P_e(r) \times 2\pi r dr \\ = \frac{1}{\pi r_{max}^2} \int_{r=0}^{r_{max}} \iiint_{B\gamma+s+R<D} f(s) ds f(B\gamma) d\gamma f(R) dR \times 2\pi r dr \quad (20)$$

In the simulation of this study, the numerical analysis of the coverage probability with Rayleigh fading is calculated by utilizing (21) in Sec. IV. Comparing the coverage probability with Rayleigh fading, the analysis of the coverage probability without Rayleigh fading is shown in [5] and represented as (21) simply.

$$\hat{P}_{cell} = \frac{1}{\pi r_{max}^2} \int_{r=0}^{r_{max}} \iint_{B\gamma+s<D} f(s) ds f(B\gamma) d\gamma \times 2\pi r dr \quad (21)$$

#### IV. PERFORMANCE EVALUATION

The flowchart of the IEEE 802.16e system for the simulation in this paper is shown in Fig. 2. To overcome the inter-symbol interference (ISI), the cycle prefix (CP) is utilized. According to the IEEE 802.16e specification [1, 8], the setup parameters are demonstrated in Table 2. The QPSK modulation is used in this simulation. The FFT size is 512. The number of data subcarriers is 360, the number of pilot subcarriers is 60, and the number of null subcarriers is 92. The FEC is not used in order to save the consuming time of the simulation. The channel Bandwidth is 5 MHz. The operating frequency is 2.5GHz. The subcarrier frequency spacing is 10.94 kHz. The OFDM symbol duration is 114.2  $\mu$ s, while the CP duration is 22.8  $\mu$ s. The SUI-1 and SUI-6 channels are used and their parameters are shown in Table 3 [6].

Fig. 3 shows the BER over the AWGN, SUI-1 and SUI-6 channels. While the BER is  $10^{-4}$ , the required SNRs for the BER over the SUI-1 and SUI-6 channels are more than that over the AWGN channel, i.e. increasing by about 1 dB and 7 dB, respectively. After obtaining the required SNR under  $BER=10^{-4}$ , the receiver sensitivity can be calculated by (13), and then the maximum allowed path loss can be calculated by (12). The link-budget is shown in Table 4. The transmission power is 46 dBm, and the transmission antenna gain is 17 dB. The height of the transmitter antenna is 80 m, and the height of the receiver antenna is 10 m.  $X_f$  and  $X_h$  can be calculated from (4) and (5), respectively. Then, Table 5 shows the receiver sensitivity and the maximum allowed path loss of the SUI-1 and SUI-6 channels. When the threshold BER is  $10^{-4}$ , the

required SNRs of the SUI-1 and SUI-6 channels are 11.8 dB and 17.2 dB, respectively. Therefore, the receiver sensitivities of both channels are -84.2478 dBm and -78.8478 dBm, respectively. Then, the maximum allowed path losses of the SUI-1 and SUI-6 channels are 147.2478 dB and 141.8478 dB, respectively. After the maximum allowed path loss is obtained, the coverage probability with and without Rayleigh Fading can be calculated by (20) and (21) respectively. Fig. 4 and 5 show the coverage probability with and without Rayleigh fading versus cell radius over the SUI-1 and SUI-6 channels, respectively. Table 6 shows the cell radius of the SUI-1 and SUI-6 channels without and with Rayleigh fading under the coverage probability of 99%. For the SUI-1 channel, the cell radius without Rayleigh fading is 4198 m, and the cell radius with Rayleigh fading is 3524 m. The cell radius with Rayleigh fading is less than that without Rayleigh fading, i.e. decreasing by 674 m. For the SUI-6 channel, the cell radius without Rayleigh fading is 1327 m, and the cell radius with Rayleigh fading is 1123 m. The cell radius with Rayleigh fading is less than that without Rayleigh fading, i.e. decreasing by 204 m. Therefore, the simulation result depicts that the cell radius may get smaller when Rayleigh fading is considered into the propagation model.

## V. CONCLUSION

The relationship between coverage probability and cell radius of the IEEE 802.16 system is determined by different wireless scenarios. The SUI channel model is used as the channel model according to the IEEE 802.16 standard. This paper presents a novel coverage probability analysis scheme with Rayleigh fading for the OFDM system over the SUI channel. While BER is  $10^{-4}$  and coverage probability achieves 99%, the cell radius of the SUI-1 and SUI-6 channels with Rayleigh fading decreases by 674 m and 204 m, respectively. It is foreseen that the cell radius becomes smaller when the SUI channel with Rayleigh fading is considered. Thus, the simulation result show that transmission ranges of the SUI-1 and SUI-6 channels with Rayleigh fading decreases to 16.1 % and 15.4% less than those without Rayleigh fading, respectively.
