Unsteady Heat and Mass Transfer in MHD Flow of Nanofluids over Stretching Sheet with a Non-Uniform Heat Source/Sink

Bandaris Shankar, Yohannes Yirga

Abstract—In this paper, the problem of heat and mass transfer in unsteady MHD boundary-layer flow of nanofluids over stretching sheet with a non uniform heat source/sink is considered. The unsteadiness in the flow and temperature is caused by the time-dependent stretching velocity and surface temperature. The unsteady boundary layer equations are transformed to a system of non-linear ordinary differential equations and solved numerically using Keller box method. The velocity, temperature, and concentration profiles were obtained and utilized to compute the skin-friction coefficient, local Nusselt number, and local Sherwood number for different parameters for heat source/sink. A comparison of the numerical results of the present study with previously published data revealed an excellent agreement.

Keywords—Magnetohydrodynamics, nanofluid, non-uniform heat source/sink, unsteady.

I. INTRODUCTION

The study of boundary layer flow of an electrically conducting fluid has many applications in manufacturing and natural process which include cooling of electronic devices by fans, cooling of nuclear reactors during emergency shutdown, cooling of an infinite metallic plate in a cooling bath, textile and paper industries, glass-fiber production, manufacture of plastic and rubber sheets, the utilization of geothermal energy, the boundary layer control in the field of aerodynamics, food processing, plasma studies and in the flow of biological fluids.

Magnetohydrodynamics (MHD) is the study of the flow of electrically conducting fluids in a magnetic field. Many experimental and theoretical studies on conventional electrically conducting fluids indicate that magnetic field markedly changes their transport and heat transfer characteristics.

The unsteady boundary layer flow over a stretching sheet has been studied by Devi et al. [1], Elbashbeshy and Bazid [2], Tsai et al. [3] and Ishak [4].

Fluid heating and cooling are important in many industries such as power, manufacturing, transportation, and electronics.

Effective cooling techniques are greatly needed for cooling any sort of high-energy device. Common heat transfer fluids such as water, ethylene glycol, and engine oil have limited/poor heat transfer capabilities due to their low heat transfer properties. In contrast, metals have thermal conductivities up to three times higher than these fluids, so it is natural that it would be desired to combine the two substances to produce a heat transfer medium that behaves like a fluid, but has the thermal conductivity of a metal. A lot of experimental and theoretical researches have been made to improve the thermal conductivity of these fluids. In 1993, during an investigation of new coolants and cooling technologies at Argonne national laboratory in U.S, Choi invented a new type of fluid called Nanofluid [5]. Nanofluids are fluids that contain small volumetric quantities of nanometer-sized particles, called nanoparticles. The nanoparticles used in nanofluids are typically made of metals (Al, Cu, Ag, Au, Fe), oxides (Al₂O₃, CuO, TiO₂), metal carbides (SiC), nonmetals (graphite carbon nanotubes), nitrides (AlN, SiN), and others. Common base fluids include water, ethylene glycol and oil. Nanofluids commonly contain up to a 5% volume fraction of nanoparticles to see effective heat transfer enhancements. Nanofluids are studied because of their heat transfer properties: they enhance the thermal conductivity and convective properties over the properties of the base fluid. Moreover, the presence of the nanoparticles enhance the electrical conductivity property of the nanofluids, hence are more susceptible to the influence of magnetic field than the conventional base fluids. The suspended metallic or nonmetallic nanoparticles change the transport properties and heat transfer characteristics of the base fluid, hence enhance the heat transfer of the base fluid. Typical thermal conductivity enhancements are in the range of 15-40% over the base fluid and heat transfer coefficient enhancements have been found up to 40% [6].

Nanofluids have enhanced thermophysical properties such as thermal conductivity, thermal diffusivity, viscosity and convective heat transfer coefficients compared to those of base fluids. Thermophysical properties of nanofluids have been studied by, among others, Kang et al. [7], Velagapudi et al. [8] and Rudyak et al. [9].

After the pioneer investigation of Choi, thriving experimental and theoretical researches were undertaken to discover and understand the mechanisms of heat transfer in nanofluids. The knowledge of the physical mechanisms of heat transfer in nanofluids is of vital importance as it will
enable the exploitation of their full heat transfer potential. Masuda et al. [10] observed the characteristic feature of nanofluid is thermal conductivity enhancement. This observation suggests the possibility of using nanofluids in advanced nuclear systems [11]. A comprehensive survey of convective transport in nanofluids was made by Buongiorno [12], who says that a satisfactory explanation for the abnormal increase of the thermal conductivity and viscosity is yet to be found. He focused on further heat transfer enhancement observed in convective situations. Khan and Pop [13] presented a similarity solution for the free convection boundary layer flow past a horizontal flat plate embedded in a porous medium filled with a nanofluid. Makinde and Aziz [14] studied MHD mixed convection from a vertical plate embedded in a porous medium with a convective boundary condition.

The interaction of magnetic field with nanofluids have several potential applications and may be used to deal with problems such as cooling of nuclear reactors by liquid sodium and induction flow meter which depends on the potential difference in the fluid in the direction perpendicular to the motion and to the magnetic field [15]. During chemotherapy failure to provide localized drug targeting, results in an increase of toxic effects on neighboring organs and tissues, this is precisely done by magnetic drug targeting. This technology is based on binding established anticancer drugs with magnetic nanoparticles (ferrofluids) that concentrate the drug in the area of interest (tumor site) by means of magnetic fields. Recently, the application of magnetohydrodynamics in the polymer industry and metallurgy has attracted the attention of many researchers. Several researches investigated the MHD flow [16]–[22].

Majority of the studies are restricted to boundary layer flow and heat transfer in Newtonian fluids. However, due to the increasing importance of nanofluids in recent years a great attention has been given to the study of convective transport of nanofluids together with the magnetohydrodynamics. In addition to this the unsteady flow of nanofluids with a non uniform heat source/sink has been given less attention. Therefore, the aim of the present paper is to study the unsteady magnetohydrodynamic flow and heat transfer of nanofluids over stretching sheet with non uniform heat source/sink. The combined effect of all the above mentioned parameters has not been reported so far in the literature, which makes the present paper unique.

The governing highly nonlinear partial differential equation of momentum, energy and concentration fields have been simplified by using suitable similarity transformations and then solved numerically with the help of a powerful, easy to use method called the Keller box method. This method has already been successfully applied to several non linear problems corresponding to parabolic partial differential equations. As discussed in [23] the exact discrete calculus associated with the Keller-Box Scheme is shown to be fundamentally different from all other mimic numerical methods. The box-scheme of Keller is basically a mixed finite volume method, which consists in taking the average of a conservation law and of the associated constitutive law at the level of the same mesh cell.

II. MATHEMATICAL FORMULATION

Consider a two-dimensional unsteady laminar boundary layer flow of nanofluids over a continuously stretching sheet. At time $t = 0$, the plate is impulsively stretched with a velocity $U_w(x,t) = bx/(1 - at)$ where $a$ and $b$ are positive constants. If we consider the Cartesian coordinate system with the origin fixed in such a way that, the $x$-axis is taken along the direction of the continuous stretching surface and the $y$-axis is measured normal to the surface of the sheet as shown schematically in Fig. 1. The fluid is electrically conducting under the influence of an applied magnetic field $B(x)$ normal to the stretching surface. Since the magnetic Reynolds number is very small for most fluid used in industrial applications it is assumed that the induced magnetic field is negligible in comparison to the applied magnetic field. The fluid is a water based nanofluid containing two different types of nanoparticles; Alumina and copper nanoparticles. It is assumed that the base fluid and the nanoparticles are in thermal equilibrium and no slip occurs between them. The nanofluid motion is caused solely by the stretching of the sheet. The surface is assumed to have a non-uniform internal heat generation/absorption and the surface temperature and concentration varies with the coordinate $x$ and time $t$. The thermophysical properties of the nanofluid are given in Table I (see Oztop and Abu-Nada [24]).
\[
\frac{\partial T}{\partial t} + u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} = \alpha_nf \frac{\partial^2 T}{\partial y^2} + \frac{1}{(\rho c_p)_n} q''' \\
\frac{\partial C}{\partial t} + u \frac{\partial C}{\partial x} + v \frac{\partial C}{\partial y} = D \frac{\partial^2 C}{\partial y^2} + \frac{\partial}{\partial y} \left( \nu \frac{\partial C}{\partial y} \right)
\]

where \( t \) is the time, \( u \) and \( v \) are the velocity components in the \( x \) and \( y \) directions respectively, \( T \) and \( C \) are the temperature and concentration of the nanofluid, respectively. \( B \) is the uniform magnetic field strength, \( \sigma \) is the electrical conductivity, \( c_p \) is the specific heat at constant pressure, \( D \) is the species diffusivity, \( q''' \) is the non uniform heat generated (\( \geq 0 \)) or absorbed (\( \leq 0 \)) per unit volume. \( \mu_{nf}, \rho_{nf}, \alpha_{nf}, \) and \((\rho c_p)_{nf}\) are the dynamic viscosity, density, thermal diffusivity, and heat capacitance of the nanofluid, respectively, which are given as \([25], [26]:\)

In which \( \nu_f, \mu_f, \rho_f, K_f \) are the kinematic viscosity, dynamic viscosity, density, and thermal conductivity of the base fluid respectively. \( \rho_x k_x, (\rho c_p)_x \) are the density, thermal conductivity, and heat capacitance of the nanoparticle respectively. \( \phi \) is the solid volume fraction of nanoparticles and \( k_{nf} \) is thermal conductivity of the nanofluid.

The value of \( q''' \) is chosen approximately as in Abo-Eldahab and Aziz [27].

\[
q''' = \frac{k_{nf} U_w}{x \nu_f} \left[ A'(T_w - T_0) e^{-\eta} + B'(T - T_0) \right]
\]

where \( A' \) and \( B' \) are parameters of space dependent and temperature dependent heat generation/absorption. It is noted that both \( A' \) and \( B' \) are positive to internal heat source and negative to internal heat sink.

The associated boundary conditions to the flow problem can be written as

\[
\begin{align*}
T &= T_w = T_\infty + T_{ref} \frac{b x}{2 v_f} (1 - at)^2 \quad \text{at} \quad y = 0 \\
C &= C_w = C_\infty + C_{ref} \frac{b x}{2 v_f} (1 - at)^2 \\
u &\rightarrow 0, T \rightarrow T_\infty, C \rightarrow C_\infty \quad \text{as} \quad y \rightarrow \infty
\end{align*}
\]

In which \( a \) and \( b \) are constants. \( T_w \) and \( C_w \) are the temperatures and concentration of the sheet, respectively. \( T_{ref} \) and \( C_{ref} \) are constant reference temperature and concentration, respectively. \( T_\infty \) and \( C_\infty \) are the temperature and concentration of the nanofluid far away from the sheet, respectively. In this study, the sheet is assumed to be heated and its temperature and concentration is higher compared to the free stream temperature \( T_\infty \) and concentration, \( C_\infty \).

To obtain similarity transformation, it is assumed that the magnetic field \( B(x) \) is of the form:

\[
B(x) = \frac{b \theta}{(1 - at)^{1/3}}
\]

where \( B_0 \) is the constant magnetic field.

Introducing the following similarity transformations

\[
\eta = \frac{y}{\sqrt{\nu (1 - at)}}, \quad u = \frac{b x}{1 - at} \frac{f(\eta)}{\sqrt{(1 - at) f(\eta)}}, \quad v = -\frac{b v_f}{1 - at} \frac{f'(\eta)}{\sqrt{(1 - at) f(\eta)}}
\]

\[
\theta(\eta) = \frac{T - T_\infty}{T_w - T_\infty}, \quad h(\eta) = \frac{C - C_\infty}{C_w - C_\infty}
\]

Making use of (8), the continuity (1) is automatically satisfied and (2)-(4) and (7) reduces to

\[
f''' + \phi_1 \left[ f f'' - f^2 - S(1 - \frac{1}{2} \eta f'') - \frac{M}{P_f^2} f' \right] = 0
\]

\[
\theta'' + \phi_2 Pr \frac{k}{k_{nf}} \left[ \theta' - \frac{1}{2} S(3 \theta + \eta \theta') + A' e^{-\eta} + B' \theta \right] = 0
\]

\[
h'' + Le(f h' - 2f' h - \frac{1}{2} S(3 h + \eta h')) = 0
\]

with boundary conditions

\[
f(0) = 0, f'(0) = 1, \theta(0) = 0, h(0) = 1, \quad f'(\eta) \rightarrow 0, \theta(\eta) \rightarrow 0, h(\eta) \rightarrow 0, \text{as} \eta \rightarrow \infty
\]

where \( f(\eta), \theta(\eta) \) and \( h(\eta) \) are the dimensionless velocity, temperature and nanoparticle concentration, respectively, primes denote differentiation with respect to the similarity variable \( \eta \). \( S = \frac{b}{b} M = \frac{\alpha b^2}{P_f b}, Pr = \frac{r_f (\rho f)_f}{k_f} \) and \( Sc = \frac{v_f}{D} \) represent the unsteadiness parameter, magnetic parameter, Prandtl number and Schmidt number, respectively and the constants \( \phi_1, \phi_2 \) and \( \phi_3 \) that depend on the nanoparticle volume fraction are given by

\[
\phi_1 = (1 - \phi)^{0.5} \left( 1 - \phi + \phi \frac{b x}{2 v_f} \right), \quad \phi_2 = 1 - \phi + \phi \frac{b x}{2 v_f}, \quad \phi_3 = 1 - \phi + \phi \frac{b x}{2 v_f}
\]

The physical quantities of interest in this problem are the local skin friction coefficient \( C_f \), the Nusselt number \( Nu_x \), which represents the rate of heat transfer at the surface of the plate and the local Sherwood number \( Sh_x \), which represents
the rate of mass transfer at the surface of the plate, which are defined as

\[ C_f = \frac{2\tau_w}{\rho u_w^2}, N_u_x = \frac{x_{u_w}}{k_f(T_w-T_{inf})}, S_h_x = \frac{x_{h_w}}{D(T_w-T_{inf})} \quad (14) \]

where \( \tau_w \) is the skin friction, \( q_w \) is the heat flux and \( J_w \) is the mass flux through the plate, which are given by

\[ \tau_w = -\mu_f \frac{\partial u}{\partial y} \bigg|_{y=0} \]
\[ q_w = -k_f \frac{\partial T}{\partial y} \bigg|_{y=0} \]
\[ J_w = -D \frac{\partial c}{\partial y} \bigg|_{y=0} \quad (15) \]

Making use of (8) and (5) in (14), the dimensionless skin friction coefficient, wall heat and mass transfer rates are obtained as

\[ C_f (1-\phi)^{2.5} \frac{1}{Re_x} \frac{n}{Re_x} = -2f''(0), \]
\[ \frac{N_u_x}{\sqrt{Re_x} \mu_f} = -\theta'(0), \]
\[ \frac{S_h_x}{\sqrt{Re_x}} = -h'(0) \quad (16) \]

where \( Re_x = \frac{x_{u_w}}{\nu_f} \) is the local Reynolds number.

III. NUMERICAL SOLUTIONS

The system of non linear ordinary differential equations (9) - (11) together with the boundary condition (12) were solved numerically using a very efficient finite difference scheme known as Keller box method. The scheme employed is the box method developed by Keller [23]. This method has been shown to be particularly accurate for parabolic problems. It is much faster, easier to program and it is chosen because it seems to be the most flexible of the common methods, being easily adaptable to solving equations of any order. The Keller-box method is essentially an implicit finite difference scheme, which has been found to be very suitable in dealing with nonlinear problems. Details of the method may be found in many recent publications, and here we have used the procedure outlined in Cebeci and Bradshaw [28].

One of the basic ideas of the box method is to write the governing system of equations in the form of a first order system. First derivatives of \( u \) and other quantities with respect to \( \eta \) must therefore be introduced as new unknown functions. With the resulting first order equations, the "centered-difference" derivatives and averages at the midpoints of net rectangles and net segments are used, as they are required to get accurate finite difference equations. The resulting finite difference equations are implicit and nonlinear. Newton's method is first introduced to linearize the nonlinear system of equations before a block-tridiagonal factorization scheme is employed on the coefficient matrix of the finite difference equations. The solution of the linearized system of difference equations can be obtained in a very efficient manner by using the block-elimination method [28]. In this study a uniform grid of size \( \Delta\eta = 0.01 \) is chosen to satisfy the convergence criteria of \( 10^{-6} \), which gives about a four decimal places accuracy for most of the prescribed quantities.

IV. RESULTS AND DISCUSSION

We have studied heat and mass transfer in nanofluids unsteady flow due to a stretching sheet with non-uniform heat source/sink. We considered two different types of nanoparticles, namely, Alumina and Copper, with water as the base fluid (i.e. with a constant Prandtl number \( Pr = 6.2 \)). The thermophysical properties of the nanofluids were assumed to be functions of the volume fraction. The transformed non linear equations (9) - (11) subjected to the boundary condition (12) was solved numerically using Keller box method, which is described in Cebeci and Bradshaw [28]. The velocity, temperature, and concentration profiles were obtained and utilized to compute the skin-friction coefficient, the local Nusselt number, and local Sherwood number in (16). The numerical results for different values of the governing parameters viz., nanoparticle volume fraction \( \phi \), unsteadiness parameter \( S \), magnetic field parameter \( M \), Schmidt number \( Sc \), space-dependent parameter \( A^* \) and temperature-dependent parameter \( B^* \) for heat source/sink are presented in graphs. In the absence of nanoparticles, to validate the accuracy of our results a comparison has been made with previously reported works in the literature. The comparisons are found to be in an excellent agreement (see Tables II and III).

The skin friction coefficients for different values of the magnetic parameter \( M \) are given in Table II. It can be seen from Table II that the magnitude of \( f''(0) \) increases with an increase in \( M \). Increasing values of \( M \) resulted in a considerable opposition to the flow due to a Lorenz drag force which causes the values of skin friction coefficient to increase. Moreover, the comparison of the results with the exact solution (17) and ADM-Pade [29] revealed a good agreement.

\[ f(\eta) = \frac{1 - e^{-\sqrt{1+M\eta}}}{\sqrt{1+M}}, f''(0) = -\sqrt{1+M} \quad (17) \]

The heat transfer coefficients are shown in Table III for different values of the Prandtl number \( Pr \) and the temperature-dependent parameter \( B^* \) for heat source/sink. It can be observed that the rate of heat transfer increases with increasing values of \( Pr \) and decreasing values of \( B^* \). The present results showed a good agreement with the earlier findings by Vajravelu and Ropper [30] and Tsai et al. [3].

The following figures show a comparison on the flow, heat and mass transfer characteristics between the $Al_2O_3$–water nanofluid (plotted by solid lines) and Cu–water nanofluid (plotted by dashed lines).

**Fig. 2** Velocity distribution $f'(\eta)$ of $Al_2O_3$–water and Cu–water nanofluids, when $\phi = 0.2$, $M = S = 1$, $Pr = 6.2$, $A^* = B^* = 0.05$, $Sc = 1$

**Fig. 3** Effects of $S$ on the velocity distribution $f'(\eta)$, when $\phi = 0.2$, $M = 1$, $Pr = 6.2$, $A^* = B^* = 0.05$, $Sc = 1$ in case of $Al_2O_3$–water and Cu–water nanofluids

**Fig. 4** Effects of $S$ on the temperature distribution $\theta(\eta)$, when $\phi = 0.2$, $M = 1$, $Pr = 6.2$, $A^* = B^* = 0.05$, $Sc = 1$ in case of $Al_2O_3$–water and Cu–water nanofluids
Fig. 5 Effects of $S$ on the concentration profile $h(\eta)$, when $\phi = 0.2, M = 1, Pr = 6.2, A^* = B^* = 0.05, Sc = 1$ in case of $Al_2O_3$ - water and $Cu$ - water nanofluids.

Figs. 6 and 7, present the effect of the spaced dependent and temperature dependent heat source/sink parameters $A^*$ and $B^*$, respectively, on the temperature profile for both the $Al_2O_3$ - water and $Cu$ - water nanofluids. Fig. 6 illustrates, that the temperature profile increases with increasing values of $A^*$. This is because, with an increase in the value of $A^* > 0$ (heat source), the boundary layer generates energy which causes the temperature profile to increase. Where as in the case of $A^* < 0$ (absorption), the boundary layer absorbs energy causing the temperature of the nanofluid to fall considerably with decreasing values of $A^* < 0$. It can also be observed that the temperature profile is slightly higher in the $Al_2O_3$ - water nanofluid than in the $Cu$ - water nanofluid.

Fig. 7 demonstrates that, the temperature profile increases with increasing the values of the temperature dependent heat source/sink parameter $B^*$, in both the $Al_2O_3$ - water and $Cu$ - water nanofluids. Thus energy is released when $B^* > 0$ which causes the temperature of the fluid to increase, whereas when the energy is absorbed by decreasing the values of $B^* < 0$, the temperature drops significantly near the boundary layer. Moreover the temperature drops slightly faster in the $Cu$ - water than in the $Al_2O_3$ - water nanofluid with decreasing the values of $B^*$.

Fig. 8 shows, the effect of the Schmidt number $Sc$ on the concentration profile. It is noted that the concentration profile decreases with an increase in the value of $Sc$ for both the $Al_2O_3$ - water and $Cu$ - water nanofluids. This is due to the decrease in the decrease in the solutal boundary layer thickness. Moreover, the concentration boundary layer thickness of the $Cu$ - water nanofluid is thicker than the $Al_2O_3$ - water nanofluid.
Figs. 9-13 illustrate the effects of various parameters on the skin friction, rate of heat and mass transfer at the wall in case of the $\text{Al}_2\text{O}_3$ – water and Cu-water nanofluids.

Fig. 9 shows the variation of the wall skin friction coefficient with the nanoparticle volume fraction $\phi$ for different values of the magnetic parameter $M$ in case of the $\text{Al}_2\text{O}_3$ – water and Cu – water nanofluids. It is noted that the wall skin friction coefficient is an increasing function of $\phi$ for Cu – water nanofluid and decreasing function of $\phi$ for the $\text{Al}_2\text{O}_3$ – water nanofluid, while the skin friction coefficient increases with an increase in $M$ in both the $\text{Al}_2\text{O}_3$ – water and Cu – water nanofluids. Moreover, the wall skin friction is higher in the Cu – water nanofluid compared to the $\text{Al}_2\text{O}_3$ – water nanofluid. Thus, the Cu – water nanofluid gives a higher drag force in opposition to the flow as compared to the $\text{Al}_2\text{O}_3$ – water nanofluid.

Fig. 10, present the effects of the nanoparticle volume fraction $\phi$ and Magnetic parameter $M$ on the local Nusselt number $\theta^\prime(0)$, which is a measure of rate of heat transfer at the wall. It is clear that, the wall heat transfer rate decreases with increasing the nanoparticle volume fraction and magnetic parameter in both $\text{Al}_2\text{O}_3$ – water and Cu – water nanofluids. In addition to this, the rate of heat transfer at the wall is higher in $\text{Al}_2\text{O}_3$ – water nanofluid than in Cu – water nanofluid.

The combined effect of the space dependent $A^\prime$ and temperature dependent $B^\prime$ heat source/sink parameters on the wall heat transfer rate is shown in Fig. 11 in case of $\text{Al}_2\text{O}_3$ – water and Cu – water nanofluids. The rate of heat transfer is a decreasing function of $A^\prime$ and $B^\prime$ in both fluids. Moreover, the rate of heat transfer at the wall is less in case of the Cu – water nanofluid compared to the $\text{Al}_2\text{O}_3$ – water nanofluid.

Figs. 12 and 13 show the variation of mass transfer rate, Sherwood number, with different parameters. Fig. 12 shows the variation of the mass transfer rate at the plate surface with $\phi$ for different values of the magnetic parameter $M$ in case of $\text{Al}_2\text{O}_3$ – water and Cu-water nanofluids. The rate of mass transfer decreases with increasing $M$ and $\phi$, while it increases with $\phi$ in case of $\text{Al}_2\text{O}_3$ – water nanofluid. The Sherwood number increases with an increase in $S$ and Sc (see Fig. 13). In Figs. 12 and 13, it is observed that the $\text{Al}_2\text{O}_3$ – water nanofluid has higher rate of mass transfer than the Cu – water nanofluid.
and our results revealed, among others, the following.

- The concentration profile is observed to decrease with increasing \( S \) and \( Sc \), and decrease with \( M \) and \( \phi \), while it increase with \( \phi \) in case of \( Al_2O_3 \) – water nanofluid. The \( Al_2O_3 \) – water nanofluid has higher rate of mass transfer than the \( Cu \) – water nanofluid.

A comparison with previously reported data is made and an excellent agreement is noted.
