

Attachment and Self Esteem among Adolescents of Separated Parents

Authors : Aswathy Sampath

Abstract : The study examined the levels of self esteem and attachment among adolescents of divorced and non-divorced parents. Adolescent is a period which is most prodigious yet stressful period of development in a human's life hence it is important to study the effects on them. The study was conducted on total 60 adolescents, 30 in each group, from the area of Trivandrum, Kerala as it is the top rated in the number of divorce cases in India. The data was collected using Rosenberg's self esteem scale and IPPA (father, mother and peer) The results of this study were analyzed using t test and found that there is no significance difference in the level of self esteem and attachment (father, mother and peer). This is due to the cultural elements that give support to the individual and also the type of family as it is much different from the west. Although, there was no significant result, there were higher mean scores in the attachment towards peer for children who are from separated family background or in other words adolescents whose parents were divorced. This tells us the essence of social support.

Keywords : adolescent, attachment, self esteem, separation
