

Non-Invasive Imaging of Human Tissue Using NIR Light

Authors : Ashwani Kumar

Abstract : Use of NIR light for imaging the biological tissue and to quantify its optical properties is a good choice over other invasive methods. Optical tomography involves two steps. One is the forward problem and the other is the reconstruction problem. The forward problem consists of finding the measurements of transmitted light through the tissue from source to detector, given the spatial distribution of absorption and scattering properties. The second step is the reconstruction problem. In X-ray tomography, there is standard method for reconstruction called filtered back projection method or the algebraic reconstruction methods. But this method cannot be applied as such, in optical tomography due to highly scattering nature of biological tissue. A hybrid algorithm for reconstruction has been implemented in this work which takes into account the highly scattered path taken by photons while back projecting the forward data obtained during Monte Carlo simulation. The reconstructed image suffers from blurring due to point spread function.

Keywords : NIR light, tissue, blurring, Monte Carlo simulation

Conference Title : ICMBSE 2015 : International Conference on Medical and Biological Systems Engineering

Conference Location : Paris, France

Conference Dates : July 20-21, 2015
