## **Prosthesis Design for Bilateral Hip Disarticulation Management**

Authors : Mauricio Plaza, Willian Aperador

**Abstract :** Hip disarticulation is an amputation through the hip joint capsule, removing the entire lower extremity, with a closure of the remaining musculature over the exposed acetabulum. Tumors of the distal and proximal femur were treated by total femur resection; a hip disarticulation sometimes is a performance for massive trauma with crush injuries to the lower extremity. This article discusses the design a system for rehabilitation of a patient with bilateral hip disarticulations. The prosthetics designed allowed the patient to do natural gait suspended between parallel articulate crutches with the body weight support between the crutches. The care of this patient was a challenge due to bilateral amputations at such a high level and the special needs of a patient mobility.

Keywords : amputation, prosthesis, mobility, hemipelvectomy

Conference Title : ICMISC 2014 : International Conference on Medical Image and Signal Computing

Conference Location : Bali, Indonesia

Conference Dates : October 09-10, 2014
