The Non-Existence of Perfect 2-Error Correcting Lee Codes of Word Length 7 over \( \mathbb{Z} \)

Authors: Catarina Cruz, Ana Breda

Abstract: Tiling problems have been capturing the attention of many mathematicians due to their real-life applications. In this study, we deal with tilings of \( \mathbb{Z}^n \) by Lee spheres, where \( n \) is a positive integer number, being these tilings related with error correcting codes on the transmission of information over a noisy channel. We focus our attention on the question 'for what values of \( n \) and \( r \) does the \( n \)-dimensional Lee sphere of radius \( r \) tile \( \mathbb{Z}^n \)?'. It seems that the \( n \)-dimensional Lee sphere of radius \( r \) does not tile \( \mathbb{Z}^n \) for \( n \geq 3 \) and \( r \geq 2 \). Here, we prove that is not possible to tile \( \mathbb{Z}^n \) with Lee spheres of radius 2 presenting a proof based on a combinatorial method and faithful to the geometric idea of the problem. The non-existence of such tilings has been studied by several authors being considered the most difficult cases those in which the radius of the Lee spheres is equal to 2. The relation between these tilings and error correcting codes is established considering the center of a Lee sphere as a codeword and the other elements of the sphere as words which are decoded by the central codeword. When the Lee spheres of radius \( r \) centered at elements of a set \( M \subset \mathbb{Z}^n \) tile \( \mathbb{Z}^n \), \( M \) is a perfect \( r \)-error correcting Lee code of word length \( n \) over \( \mathbb{Z} \), denoted by \( \text{PL}(n, r) \). Our strategy to prove the non-existence of \( \text{PL}(7, 2) \) codes are based on the assumption of the existence of such code \( M \). Without loss of generality, we suppose that \( O \in M \), where \( O = (0, \ldots, 0) \). In this sense and taking into account that we are dealing with Lee spheres of radius 2, \( O \) covers all words which are distant two or fewer units from it. By the definition of \( \text{PL}(7, 2) \) code, each word which is distant three units from \( O \) must be covered by a unique codeword of \( M \). These words have to be covered by codewords which dist five units from \( O \). We prove the non-existence of \( \text{PL}(7, 2) \) codes showing that it is not possible to cover all the referred words without superposition of Lee spheres whose centers are distant five units from \( O \), contradicting the definition of \( \text{PL}(7, 2) \) code. We achieve this contradiction by combining the cardinality of particular subsets of codewords which are distant five units from \( O \). There exists an extensive literature on codes in the Lee metric. Here, we present a new approach to prove the non-existence of \( \text{PL}(7, 2) \) codes.
